Plate DLIII. fig. 2. will illuftrate the proper method of laying an ambufcade. A reprefents the infantry of the furprifing party, which ought to be placed at lealt 600 paces behind \(B\), the cavalry, fo that, if purfued, they may both fall back to \(A\), and make good their retreat to the guard at the bridge or crofs road; or to another party of infantry placed in ambuth half way. If the ambufcade be placed in a srood, an intelligent non-commiflioned officer fhould be chofen to get upon a high tree C , from which he can fee the march of the enemy, and give notice of the motl effential circumfrances. The firft of thefe is the feeing the advanced guard; the Second is the approach of the corps, and the third is the time when their front is advanced as far as the ambufeade B ; for which the commanding officer fhould inftruef the obferver what fignals he is to make from the top of the tree, to communicate the neceffary information without fpeaking, which may be done by means of a fmall cord D , of a brown or green colour, fo as to be leaft perceptible. Let this cord be placed as in the plan, fo that no branch interrupt it, with one end in the hand of the obferver, and the other in the commanding officer's hand in the ambulcade \(\mathbf{B}\).

As foon as the advanced guard appears, the obferver muit pull the cord, and the commanding officer caufe the party to mount and remain in deep filence. If by a Atratagem, which is praftifed for particular reafons, the advanced guard is immediately followed by the corps, which may ie eafily known by their being more numerous than ordinary, and not Sllowed by any other corps, that the commander may not be deceived by the enemy, the cord hould be drawn a fecond lime, and a third time when their front is advanced as high as the ambufcade. At that inftant the party muft rufh out; and furioufly attack the flanks of their centre in the fol. lowing manner.

If the advanced guard E is formed only of an ordinary number, they fhould be allowed to pafs; and at the approach of the principal part or convoy \(F\), the chief to be informed by the fecond pulling of the cord. \(A\) ' the moment the head of the convoy fhall be advanced a; high as \(B\), the cord mutt be pulled the third and laft time; and at this fignal the party mutt ruh our without being perceived, and fuddenly attack the centre on the flank, engaging only with their fwords, and \(m\)-king fuch a noife as to prevent the enemy from bearing the orders of their officers. They mult difarm all shom their bravery flall throw in their way, taking care not to frater or purfue too far, unlefs it be certain thin they are fofir from their ariny or parties, on account of which they cannot be affected; for in either of
thefe cafes they will not fail to run at tise noife, and diIturb the retreat.

In all fecret expeditions, great circumfpe 民tion hould be ufed, that the party be not feen or betrayed; as if they be difcovered by the advanced guard before the blow be ftruck, the enterprife mut be immediately abaudoned, and the party retire. When the guide, or any one of the party deferts, and cannot be catched, a reircat muft immediately be thought of, or the ambufcade muft be placed fomewhere elfe; but to prevent fuch a misfortune, the officers fhould be charged to cxâmine frequently whether they have all their men.

An ambufcade thould never be formed for cutting off the enemy's retreat, as this will drive him to defpair, and make him rally and attack the party with defperate refolution. There may be an exception to this, when it is pretty certain that the whole party of the cnemy may be cut off or taken prifoners, either from the fmallnefs of their number, or from the peculiar fituation of the place of ambulcade.

Several amhufcades mould not be formed at once, except for the purpofe of feizing foragers, in which cate they fhould be difpofed fo that the fentinels may fee from one to another. Then the firft guard which fees the foragers, fhould commence the attack, and can foon be affifted by the reft of the party.

In all ambufcades, no fentries fhould be placed but officers or non-commifioned officers. On downs, behind mountains, or in gullies, the fentries fhould lie with their bellies on the ground, and their feet towards the ambufcade, the body covered with a gray or green cloak, according to the colour of the ground, with their heads a little raifed and wrapped in a handkerchief of ftraw green colour, or white in time of fnow, fo as not to be eafily perceived. The number of fentinels cannot be determined, but they fhould be difpofed fo as to watch on all fides of the ambuicade, and ftop every one who may inadvertently approach too near. The fentries thould give notice of what they difcover by gettures, to which all the officers fhould be very attentive. In countries where there are no woods, vineyards, or hedges, an ambufeade may be placed in a field of hemp or corn, or fome fort of grain, provided it be high enough to cover the men, at leaft with the help of art. - When the flalk of the corn is not high enough, fome of the infantry muft be fet to work with fpades and pickaxes, which they muft have brought along with them, for the purpofe of digging holes in the field deep enough to make up for the defective height of the corn.

An ambufcade often forms part of a ftratagem for bringing on an action with a party of the enemy which would be fuperior, were it not for fome advantage of this kind, as in the following cafe. See Plate DLIlI. fig. 1. Suppofe the whole party to fet out from A, Fig I. marching under the conduct of a trulty guide by covered ways at a diftance from the enemy. Being come to the place \(C\), which ought to be in the environs, and as high as the field of battle, the infantry fhould be concealed out of the road far from the fight of pafiengers. This mult be the centre of correfpondence with the army ; the rendezvous of the booty, and fupport the retreat of all the cavalry, of whicb there flould be as many detachments as there are attacks pronoled to be made. We flall fuppofe fix of 100 men each, and they
tilitary muff go fecretly by particular soutes to their refpective polts, E, D, F, G, H, J. Neither trouble nor expence fhould be fpared to procure good guides. Kach detachment thould lie in ambull half a league, if necerfary, from the ohject of the attack BKKKK.

The noile of the nulketry in the armies is to be the fignal for their irruption ; and then bravery, intrepidity, and courage will give wings to the people. The fecond detachment D will glance imperceptibly between the villages, and fall likc thunder on the camp B; and while 80 attack all whom they meet, the other 20 flould light their torches at the fires that are to be found everywhere, and fipread the Hames rapidly to the ftraw of the tents. As they camnot fail to have the picquet of the camp foon at their heels, they muft frike their blow with all pollible expedition, without fopping to plunder, being content with the glory of having excited a genceal alarm, capable of coufounding the whole army, and contributing to the gaining of a battle.

At the fame time that the detachment 1 attacks the camp B, the others, \(E, F, G, H\), muft with equal violence attack the villages \(\mathrm{K}, \mathrm{K}, \mathrm{K}, \mathrm{K}\), which they have in front, doing the fame the firft did in camp, except that they may feize as plunder every thing which they can conveniently carry off, with which thefe villages are commonly filled, feizing the beft horfes, hamftringing others with the froke of a fword, and fetting fire to all the places which contain the enemy's baggage. Each detachment fhould caufe fome horfemen to advance be. yond the village, to obferve the motion of the troops, who will not fail to run to thcir affiltance. As foon as they perceive thent, they muft make their retreat as faft as poffiole by the routes which the commanding officer has preconcerted, and which are reprefented in the plate by the coare lines. The fixth detachment I, in ambuth on the fide of the road leading from the camp, fhould remain there, to feize all the enemy who think of faving themfelves by flight.

When the commander of a detachment finds himfelf obliged to abandon a poft, or that it is not worth defending, it becomes neceffary for him to prepare for his retreat. This is often a difficult and dangerous affair, and requires much prudence as well as bravery on the part bo.h of officers and men. If poffible, he flould retreat on that fide which forms a communication with the general bafis or line of pofts occupied by his party. The following obfervations on lines of retreat, connested with the lines of operation defcribed in \(\mathrm{N}^{0} 22\), will be found of importance.

A retreat on a fingle line is a fault of the utmoft magnitude, for it is evident that if the army C (fig. 8. Plate DXLVI.) retire from it towards B , along the ig. 8. line AB, the enemy may fend befides, two corps \(a, d\), againft the flanks of this army, which would feparate it at the point B , and in this cafe it would be furrounded. Nor is this the only oifadvantage, for all the country fituated to the right and left of the line \(A B\), would fall iuto the hands of the enemy; while, in a retreat, it is always a rule to cover as much of the country as poffible.

A concentric retreat is of fuch a nature, that in an extenfive pofition they fall back to one more confined, fo that the two lines of operation at the extremities \(A B\), (fig. 9.) unite at the object oi retreat C, forming an acute angle, or as at fig. 10. an obtufe angle; fuch a
retreat would have no better iffue than the former. The fame difadvantages which refult from retreats on a fingle line would likewife attend this. There is one circumHance which might induce a general to retreat in this manmer, and that is, with the view of covering any important place, a capital, for example, by taking an advantageous pofition, which is indicated by C, in the figures; the important place required to be covered would probably be at D. But neverthelefs this meafure would be ineffectual if the enemy were at all verfant in the art of war, and operated on the flanks of the army they were purfuing. 'The bell method of covering a country, which is in our rear, is to proceed againft the tlanks of the enemy which is advancing; and by this intrepid and bold movement, to change our defenfive operations into thofe of an attack.

A retrcat conducted in parallel lines, as the bafis \(A B\), Fig. 13, in four corps, \(1,2,3,4\), or the lines \(\Lambda \mathrm{C}, \mathrm{EG}, \mathrm{KH}, \mathrm{BD}\), is doubtleds better than the concentric retreats which we have juft comfidered. In tle firft place, the country is better covered by means of the parallel lines; fecordly, the enemy cannot fo eafily infult the Hanks of the retreating army, provided that this is in a condition to perform the fame manceuvre with regard to them, and thus obftruet their progrefs; laftly, they would be afraid of advancing with too much precipitation, from the moment their attention is divided by the attempt which may be made againft them. But there might be fomething ftill better attending it, viz. to retire in an eccentric dircction, as we thall fhow prefently.

The excellence of parallel retreats is maintained from the idea that they cover a country better, and likewife ftop the progrefs of an enemy, when oppofed in a direct line. Certainly this appears cvident to the eye; but the fight is often the medium only of error. It is the ignis fatuus which leads us into the mire, and the prefent intance is a proof of it. This opinion was not indeed well founded among our predcceffors, and atill lefs is it fo among the moderns. We do not now arreft the progrefs of the enemy, by prefenting ourfelves to their itrongef part, viz. their front; but on the contrary, by intercepting their flanks, which are the weakeft parts; by larafling their rear; by menacing their provifions and their communication with the fources of their vigour and power. It follows from hence, that eccentric retreats are the beff. An army (fig. 12.) who retires from \(a, b, c, d, e\), towards \(f, g, h, i, k\), runs no rifk of feeing the enemy advance in the regment \(f, k\); for tie would, by fuch a movement, be in danger of being furrounded.

We may lay it down as a rule, that it is effentially neceflary, in all retreats, to divide into different columns, in order to divert the attention of the enemy; and it is fully demouftrated that there is not in war a more important maxim. We might fhow that this method of attracting the attention of the enemy to many different points at once is, properly fpeaking, exciting a. degree of apprehenfion with regard to his flanks and rear. But it naturally refults from all that has been faid relative to the inutility of diverging offenfive operations, as well as thofe which are directed by a fingle line, or by an acute angle, that eccentric retreats are of all others the moft preferable. Since concentric operations are the mon advantageous in attacking, eccentric ones muff neceflarily poffefs the fame adraniages in defence ; every
aititary thing thould be in oppofition, in two different kinds of warfare, whicl are in their nature and interefts contradiêtory.

In conducting a retreat, as in all other field operations, an army fhould affume, as the principal object, its own magazines, and the fafety of its lines of convoy, rather than the army of the enemy; and it fhould never take a pofition oppolite the enemy, but rather on one fide

We have hitherto confidered military operations in the field, as they are fubfervient, or preparatory to, that moft important confequence of war, a battle. We muft now examine what are the caufes which frould induce a general to hazard or avoid a battle; and if he determine on a general action, what are the belt methods of difpofing the troops under his command.

At prefent, actions in the field are diftinguifhed into two kinds, according as they are more or lefs general. When the whole of the adverfe armies are engaged, it is called a battle; but where only a part of each is concerned, a combat. The latter of thefe, however defperate, does not in general involve fuch important confequences as the former ; but as in a general engagement, the vanquifhed party ufually lofe the greater part of their artillery and baggage, and are compelled to retire and leave the country behind them at the mercy of the victors, a prudent general never hazards fuch loffes without important reafons.
When an army is fuperior to its opponents in number or difcipline; when difcord prevails among the chiefs of the adverle army; when a negleet of the ordinary precautions in marching, encamping, or other obvious duties, demonfrate their incapacity; when it is neceffary to relieve a confiderable town or poft that is befieged by the enemy; when it is apprehended that the army will be difperfed or ruined, without a general engagement; when intelligence has been received that reinforcements are approaching to the enery, which will render him fuperior; when the enemy has received, in fome preceding action, a confiderable check which he bas not yet recovered, or when the army whofe general is thus canvarfing the advantages and difadvantages of a battle, is in fuch a ftate, that every thing ought to be hazarded for its relief, the commander is warranted in
36 giving battle to the enemy.
Reafons for
On the contrary, when lefs is to be hoped for from a victory than feared from a defeat; when the army is inferior either in number, courage, or difcipline, to the enemy; when it is in expectation of being reinforced by a ftrong detachment of frefh troops; when the enemy is fo advantageoully pofted that it would be impolfible to bring him to an engagement on equal terms, or to force his entrenchments; or when there is a profpect, by temporifing and declining battle, of suining the army of the enemy by difeafe, famine, or defertion, it would be wrong to place the fortune of the campaign on the iffue of a 37 battle.
Preparation When a general engagement has been refolved on,
for a batile. the general is to devife the means of carrying it into execution, fo as to have the Atrongeft prefumption of fuccefs. He is to arrange, with the officers of his ftaff, the manner in which the troops are to be divided and difpofed, or what is called the order of battle; he fhould affign to his feveral officers their rcfpective pofts, and
fee that copies of the order of battle be given to thofe that have a feparate command. The proper officers fhould tahe care that the troops under thcir command be properly armed and equipped, and that they are allowed time to reft and refrefh themfelves before the engagement. The heavy baggage, and every thing that might encumber the operations of the troops, fhould be removed, and placed at a diftance under a proper guard. A refeive flould be formed near the park of artillery, confifing of fome of the braveft and beft difciplined troops, headed by the moft experienced officers.

In time of action, the commander in chief fhould be Circum \({ }^{38}\) fo fituated as to be able to iffue his orders with the leaft ces to be difficulty, and to obferve as far as poffible the operations antended of his troops, and more efpecially the effects of the firft \({ }_{2}\) duriong \({ }^{1}\) attack. Every other general officer muft keep his own flation, to direct the charge of the troops, or to rally and re-form thofe which have been routed and difperfed. When the action becomes general, and is obfinately contefted, the commander-in-chief fhould direct the principal efforts of his troops againft that part of the enemy's line which makes the greateft refiftance, and fhould himfelf haften to this fpot, to animate his men to greater activity and exertion by his prefence and exhortations.
The artillery of the army fhould accompany the firtt line, and the remainder of the troops flould follow the movements of thofe before them, fo as to preferve the proper diftance between the lines, and march with the leaf poffible diforder and confufion. If the firt line give way, the fecond fhould march up to its relief, and either charge the enemy, or keep him employed till the firft line has time to rally and re-form. If, however, as often happens, the other lines are fruck with a panic on obferving the repalfe of their predeceffors, the referve Mould be brought up, and it is probable that their courage and refolution will reanimate the fcattered troops, and turn the fortune of the day.
In forming the order of battle, regard muft be paid \({ }_{3}^{39}\) to the nature and fituation of the place whère the battle batule. is to be fought; to the number and quality of the troops engaged, and to the mode of fighting which is moit likely to take place during the adion, or to decide the victory. There are two principal methods of forming troops in order of battle, the column and the line. The former of thefe was moft in ufe among the ancients, has been greatly recommended by Folard in his commentaries on Polybius, and practifed with the moft brilliant fuccefs by the French armies fince their portentous revolution. This order of battle is adapted chiefly to cafes where the activity of the troops can be relied on, and where much fring with muiketry or artillery is not expected to take place, and where of courfe the affair is to be decided principally by the pike or the bayonet. It is allo well calculated for a body of infantry who are to refift the attack of caralry. It is obvious that from the clofe arrangement of troops in column, this difpofition mufi expofe them more to the fre of a line, and munt endanger their being flanked or furrounded by an enemy whofe front is more extended. The relative advantages and difadvantages of the column and the line, will be more readily perceived by attending to the following principles.

From the order of battle as a bafis are deduced many inftryative
infructive principles relating to what are called lines of

Again, the line AB (fig. 14.) being attacked by the
line \(c d\), the flank B cannot extend itfelf parallel to \(c d\), if this line advances always in front towards \(A\). The if this line advances always in front towards A. The
line attacked is furrounded, and even fo preffed upon, that they muft all take flight towards A. If any troops that they muft all take flight towards \(A\). It any troops
by chance fhould endeavour to form upon the line ef, they would not have time; taken in front and in flatk by the enemy's fire, they could never relift fuch an at-
tack. The cavalry would experience the fame difadby the enemy's fire, they could never relift fuch an at-
tack. The cavalry would experience the fame difadvantages in a fimilar cale. Horfemen attacked to the
right, to the left, and in front, could not defend themvantages in a fimilar cafe. Horfemen attacked to the
right, to the left, and in front, could not defend themfelves; the celerity of the horfes, no doubt, would enfelves; the celerity of the horles, no doubt, would en-
able them to deploy quicker than the infantry; but, by the fame reafoning, the enemy's cavalry, which is advanced upon their flank, would likewife advance the vanced upon their flank, would likewife advance the
quicker from the point \(B\), towards the oppofite wing \(A\), which a corps of infantry could not poffibly do. Thus it would be equally difficult to form the line ef; everyit would be equally difficult to form the line \(e f\); every-
thing would be overthrown, and they mult retire in the greateft diforder towards A. It is hence clear that
every effort hould be made by an army in line of battle, greateft diforder towards \(A\). It is hence clear that
every effort Chould be made by an army in line of battle, to turn the enemy's flanks with its front.

Concentric lines of marching and firing well exe-
cuted, are exceedingly important. Hence it is that a fortrefs mult yield when it is befieged, as the fire from fortrefs mult yield when it is befieged, as the fire from
the fortrefs is eccentric, while that of the befiegers is concentric. Hence, too, forties from a garrifon rarely fucceed, bocaufe they are eccentric operations.

When an army is much weaker than its opponent, if
the former be compelled to an action, it flould throw itfelf on the enemies flanks; and to do this with effect, itfelf on the enemies flanks; and to do this with effect,
the enemy's front fhould be kept occupied, fo as to draw off his attention from his flanks. If the line were
long, he would have time to convey all that part oppodraw off his attention from his flanks. If the line were
long, he would have time to convey all that part oppozig. I5. fite to the fide attacked, as A (fig. 15.) into the line fite to the fide attacked, as A (fig. 15.) into the line
ef, before the attacking army ed could entirely overthrow and repulfe the flank B , which would be the objcet of their efforts. In this cafe, things would again be equal; for an engagement in front wauld take place, the iffue of which is always doubtiul. If, however, they occupy the line \(A B\), by corps fent for that purpofe, as \(g\) and \(h\), while, with a greater force, they attack in llank, then it would be impofible for any part of AP to throw themfelves into the line ef, before hasing beaten \(g h\); and the time would probably be too thort for this operation, if \(c d\) puflied in fromt in a vigor-

Vol. XX. Part II. marching and lines of firing, which coaltitute a confiderable part of the elements of modern taclics.

There are as many lines of matching arifing from the order of battle, as there are foldiers in the frit rank of the line or column, and as the foldiers approach towards the enemy, thefe lines of marching, at leall in the infantry, produce lines of firing. It is the nature and relative advantages of different lines of marching and fring that we now propofe to confider.

Let us fuppofe two lines of tronps, \(A\) and 13, fg. 13 . extended oppofite to each other, of which \(A\) is confiderably longer than \(B\) at each extremity, or, as it is termed, outfanks it. It is evident that \(H_{3}\) may be furrounded by \(A\), as from the fuperior numbers of \(\Lambda\), I3 may be attacked in Bank and rear. It is therefore evident that when the numbers are unequal, and the conten is to be decided by fring, the greater number mut prevail, if both are arranged in lines.

Again, the line \(A B\) (fig. 14.) being attacked by the
ous manner. From this it follnws that the army \(A B\), though the flronger, can do nothing better at this time than quit the field of battle, as it will Otherwife be furrounded. Now, the attacking army have nothing to do but to effect an cecentric retreat; namely, to fall back with the left wing upoas \(i k\), and with the right upon \(/ m\), provided CD do not obilruct the pathave ; for in that cale, the retreat of the right wing, or of that part of the army nearelt the flank 13 , would be on \(n\), in order to create in the cnemy \(c a\) fome folicitude for his left tlank d. It is by fuch eccentric retreats that the purfuit of the enemy is prevented. 'They dare not venture it, if they do not wih to be taken in flank themfelves, and to become in their turn expofed to an efcalade and a concentric fire, and "confequently a terrible havoc. Eccentric retreats in tactics are equally as advantageous as in Arategy. The latter kind alarm the enemy with regard to his lines of operation, and confequently prevent him from advancing; the former make him afraid of expofing his Hanlis and rear, and hinder him from purfuing.

From thefe confidcrations it appears that it is no great misfortune for an army to be attacked in its centre, and divided. If the army be divided in two at the centre, it will retire eccentrically on \(e\) and \(f\) (fig. 16.). By this movement it will throw an obflacle in the way of all farther progrefs on the part of the enemy, who has divided in the middle the dotted line \(A B\). It is impoflible for the enemy \(c d\) to advance in front between \(e\) and \(f\); they would take him in flank on both fides: he muft therefore advance in front tuwards \(e\) and \(f\), both at the fime time. In this pofition \(e\) and \(f\) might detach forces to the rear of \(c d\), and operate at once on its provifions and in its country. It would be fufficient for that to fend fome corps from their flanks to the points \(A, B\). It is likewife poffible for them to advance entirely to the left and right, if they have any magazines at \(g\) and \(h\), which neverthelefs would not be expofed by the marching of the flanks towards \(A\) and \(B\), and would always be theltered from the enterprifes of cd. A third combination likewife would be to attack immediately \(c d\), which, from its pofition, would be expofed on both its flanks. In this laft cafe, \(c d\) would have no other refource than to operate on that part of the flanks \(e\) and \(f\), which are oppofite to the points \(A, B\), to compel of to retreat, and replace its front in the direction of \(\mathrm{A}, \mathrm{B}\).

It does nat require a great body of men to occupy the front of the enemy, while the reft of the army attacks the flanks. It is beft done by means of a fcattered troop, or what the French call tirailleurs, confifting of light infantry, which are ufually inftructed in the following manner. The troop, formed into two ranks, divides in fuch a manner that there may be a face between the two, as indicated in fig. 17. The fecond rank, placed behind the intervals left by the firf, fecures its flanks. When they attack, the fecond rank, CD , palfing through the intervals of the firf \(A B\), advances to the line EF, and fires. The great advantage arifing from this, is that of forming a more extenfive front thas when they are wedged in elbow to elbow; fecondly, they keep up a more fatal fire with their mufketry, becaule each foldier, being ummolefted by the one next to him, aims better, and continues his firing without interruption; thidely, a lefs number of men is luft, becaufe 4 H
many

Nifitary many of the eriemy's balls fall in the intervals, and are \(\underbrace{\text { Thactics. }}\) confequently harmief; ; but in the following mathod all thefe advantages arc united in a more emineat degrec. He:e the difperfed foldiers do not move in right lines,
Fig. rs. but circularly, as reprefented in fig. 18 . When the firlt rank has fired, the men make a little turn to the left, and run to the place occupied by the fecond rark, the men of which advance rapidly in front to the place which the former had quited, and fire, whilc the oither rank is charging. Thus, each rank alternately advancing and returing in circles, a conttant fire is kept up on the enemy, with little hazard to the men. It mut be allowed, ho:vever, that this method will fiecceed only when the enemy fland firm; for if they ty, the former method is \(t\), be preferred.

If the attacking army be forced to retire, the tirailFig. tg. leurs that fucceed them thould 110 p at \(\mathrm{N}^{\circ} 2\). fig. 1 g. initead of proceeding as far as \(\mathrm{N}^{\circ} \mathrm{I}\); while thooc that are already at \(\mathrm{N}^{0} \mathrm{I}\). in retiring fall back farther than \(\mathrm{N}^{0}\) 2. thus each rank fucceffively falling farther and farther back, contefting every inch of ground.

It may pethaps be maintained, that it is better in attack to adopt clofe order, becaule the liries of fring being more approximate, they can keep a better fire; but it may be replied, that if they are once on the flanks of the enemy, and fufficiently near to ufe the mulket, it is then of little importance whether they attack with clofe rank c, or evi tiralleurs, becaufe in either cale the eneny mall be beaten if they charge with vigour. In fuch a pofition, it would be diffecult to thrort ons's felf in the line ef (fig. 20.) particulatly if it be occupied in front, as it ought to be, and it is necefliry, that the cavairy fh uld be near, in order to futain this attack.

The retreats of the infantry intended to occupy the Tig. 21. front AB (fig. 21), need not be either eccentric or in flank, the principal object beins to direct the attention of the army \(A B\) from his \(A:=k s\), which it is intended to attack; but thefe retrograde movenents muft be conducted direkly upon / \(f\). If the retreat be ferious, and it be really intended to abaadon the front \(A B\), and to prevent the purfuit by creating in the enemy a folicitude for his flanks, then the retreat hould be cxecuted eccentrically up \(g\) h.

Suppofe an army collected in an oblique pofition, as at CD, fig. 22. and fuppofe it is to make an attack on another army AB , coming round upon its tlank. This manoeuvre has been recommended by Folard, and was practifed long ago by Epaminondas, and in modern times by Frederick the Great. It is however generally confidered as inferior to the mode of attack illuftrated in fig. 15. and AB might eafily avoid the danger by moving along iti live towards \(f\), or taking the pofition Ag. Indeed \(A B\) is itreif, by its right wing \(A\), in fome degree enabled to act on the offenfive againf the left wing of CD, by moving round in the columns \(h i\). The confequence of this mutual manceuvring would be, that CD takes AB on its tlat k , while it is itfelf taken by AB on its own flank C ; the two parts attack. ed will be probably beaten by the attacking army, and after the combat they will hoth remain oppofite to cach other, thnugh a litile obliquely with refpect to their former front.

I is not alwaye nccefliry to te form the ranks. Sup-
wing might run difperfod towards of and there make a littie turn to the right at a certain figna!, return quickly, attack the left flank D, and give it a rolling fire from three fides, before D , in order to defend himficlf, could take the form of an axe (d'une hatche) Dr. But, in order for fuch an attack to fucceed, the enemy's cavalry muft not be near. In cafe there be any to be apprehended, the precausion to be adopted would be to form into columns. 1f, therefore, attacks and retreats take place in this namer, and, above all, if care has not been taken to fuftain and cover them with a numerous cavalry, the greaier part of the tactical evolutions of the infantry are rendicied ufelefs. It is, however, indil(enfably accefiary that the troops floculd always know how to deploy from a column into a line of battle.

Captain Rö̈cla, a Prufian officer, has difcovcred a method of deploying, which appears to be by far :he eafict and the beft yet known. During the march, the divifions proceeding on the line \(A B\) (fig. 24.) oblerve the neceflary diffances. As foon as the duvifion I enters into the line of direction AB , it is commanded to the right or left, according to the fide which they wifl to face; the following divition arrives, without clanging its flep, to the very place where the preceding one has made its quart de converfion, and performs a fimilar one; the third, the fourth, and all the reft follory the exanuple. Each diviifon having thus traveried its diflance, reaches the line of diretion, when that uhich marches directly in. front has already made room.

This method is a ftep further towards. the perfection of depleying, which is to advance in front, for the divifion 1 is obliged to make a quart de converfion to the left, before prefenting in front to the line, whinh, according to the method of Captain Röfch, this line is formed merely by a kalt from. At the fame time, a converfion is a movement which always requires many paces, becaufe it is peiformed in the fegment of a circle.

In the two methods of deploying seprectented at fig. 24. and 25. the divifions traverfe the two fmallett fides of a rightangled triangle (fee fig. 25.) The Prufians have in roduced a method, in which only the hypo henufe is deferibed: it is called the adjutant's fep. The adjutants, who know from experience the length of the front of their battalions, meafure with the gallop of their horfes on the liue of direttion, the fpace necefliary for appearing in battle (fig. 26.). Each battalion fcparates from the column, and marches by the nearell road to where their adjutants ftand, at the numbers \(\mathbf{I}, 2,3,4\), as intermediate points on the line of direction AB. As foon as the firit divifion arrives at the adjutant, it immediately deploys according to the method already defcribed. If the officers who meafure the front do not make any great miftake, the march in front mult be executed nuch more quickly than by the preceding method.

Let us now examine the beft method of throwing back a wing into a line, fo that it may not be tarned. Suppofe an oblique line at \(c d\) (fig. 2\%.) with a crotchet de formed to prevent being taken by the flank \(d\); and at the fame time, to have a line ready to repulfe cwiry attack which the enemy AB, niegh attempt on the left againft this flank. Such is the firf modfication which this kind of meftion offers to our examination. Afler this fine, on crochet, has difperfed every thing which op-
pofed its progrees, it tums, till it arrive at the prolongation of the oblique front CD , and them takes the enemy in flank.

At the battle of Liffa*, fome battalions of grenadiers
ec Prifo were placed at the extremity of the light wing of the cavalry; they overthew the troops of Wirtemburg, and performed other cffential fervices. But fuch a pofition has this defect, that it offers a flank to the cnomy, which can be enfiladed by his cannon. 'This would
ig. 2s. happen to \(c d\) (fig. 28.), as well as \(d \varepsilon\), if the line AB extended beyond, and turned the oblique tront \(c \%\). It would be poffible, by means of a fquare battalion, as d, \(e, f, g\), to cover the flank which is attacking in the oblique order, but two fides of this fquare wonld be enfiladed by the cannon of the enemy. The defence of a parallelogram is therefore much weaker than that of a perfect fquare.

Fig. 29. reprefents what the Prufians call a crimaillióre, a form extremely complicated, and liable to be enfiladed by the enemy. Another and till more complicated form of this order of battle is feen at fig. 30.

Figs. 3 r. and 32. reprefent the ordar of battle in a square, a form which is well adapted both to ftrength and convenience. When it is intended to reinforce the fquare battalion againtt cavalry, the third rank feparates from the two others, and forms by itfelf a leffer fquare, within that formed by the front and centre raaks. When this is done, if the enemy's cavalry foould penetrate into one of the angles of the firlt fquare, the inner fquare forms a falient angle by converfions to the right
1Fig. 32. and left, as reprefented by the dotted lines fig. 32 . So as by a crofs fire to drive the enemy back again.

Many have propofed to conduct retreats in various fquare battalions; but it is neceffary that they fhould be fmall fquares, compofed at the utmolt of two or thrce battalions; and it is requifite, that during the march, whether by angles or fquares, they hould obferve between each other fuch a poftion, that the fire of the one flank fhould reach to the fides of the other in order Fig. 33. to protect it. (fig. \(33 . \mathrm{N}^{\circ} \mathrm{I}, 2,3\). ). This lant battalion 3 reaches the front 1 , which lat performs the fame fervice to the rear of 3 , and to the front of \(2 ; 2\), on its fide, protects the rear both of 1 and 3 . It would be difficult in the field, for thefe different. fquares to preferve fuch a comprefled pofition, and they would be in danger of wounding or killing each other by their crofs fring. Men well experienced in war have, however, preferred retreats of infantry in fquare battalions, having the cannon in the centre or on the flanks, as reprefented in fig.
Fig. 34. 31. In executing this movement, however, the diflances are fcarcely ever preferved, efpecially when it is neceflary for a wing to deploy by a converfion during a
Fig. 35. retreat, fee fig. 35 . in order to prevent the purfuit of the enemy. In every other refpect thefe retreats being eccentric, are founded on good principles. See N \({ }^{0} 33\).

When, after a difcharge of mufketry, an army has to retire, this movement cannot be expected to be executed in order. In this cafe a flight always takes place, for otherwife there would be no reafon for quitting the -field of battle. In this fituation it is neceflary to have a line of cavalry behind the infantry, to futain them; and then it is not fo bad as is generally imagined, to fly haltily into the midn of the cavalry. It is only necef. fary that this feattered infantly fhould re-form immediaicly, in the moll convenient place, in a wood, or on an
clevation; and if they relum quichly to the charge, they will difplay more courage, than in falling bacto, flep by ftep, and lofing a number of men; for in the firt inftance it is a real and ufeful intrepidity, but in the fecond it is nothing. If there be no cavalry to fuftain them in an open place, they mut then remain united, or otherwife be cut in picces.

When it is poffible to cffect a regular retreat, the beft and eafieft method is to make a halfetum to the right with the whole line, ard to march thus, progreffivcly falling back; by this means they will fooner efcape from the fire of the cnemy than in any other manuer, and the order is much more eafily kept, which is of importance, and deferves to be preperly apprcciated. There is not a more pitiable object than a fquare battalion furrounded by tirailleurs, (fig. 36.). All their fhot are concentric, and confequently eninently effective, while thofe of the fquares are eccentric, which renders then almoft nugatory. The ranks of this unhappy fquare would foon be thinned by a well-directed fire, which could not mifs its aim; and a battalion, in this pofition, would find it impofible to elcape dellruction.

The molt esiebraied modification of the oblique front, is that made by Frederick the Great, viz. the oblique attack in rounds. Experience has not yet proved what there is peculiarly excellent in this manner of attacking; and Captain Röfch has Thewn that it is not tenable in theory. He demontteates that cacla échellon would be received by the enemy with a fuperior fire ; for the one \(c d\) (fig. 37.) if it approach the line AB, within muket hot, would be catght in its flank \(c\); which being turned, and expofed to a fide fire, would infenfibly deicribe an arch in its tear, to have its adverfary in front. The divifion of the line \(A B\), which in this cafe would pour upon the flatik \(c\) of the fichellom, \(c d\), fuch a fatal fire, would be in no way hindered by the fecond ef, which is too far off to fire; and, befides, the firt two divifions of the wing \(f\) dare not fire, at leaft not with fafety, if the echellon were 300 paces diltant, for fear of reaching them in the llank \(c\). Thus, the two divifions of the line \(A B\), which are oppofite to the \(\varepsilon\) chellon, \(c d\), would continue their fie upon the fatal ank \(c\), without the leaft interruption. If they be not more than 50 or 100 paces ditant, the fe inconveniences will not take place ; but at the farme time, the advantages which were expected to refult from an attack en cichellon will be loft. Thefe advantages are, that, by dividing the front, only one part is liable to be beaten, as the others would be neglected; while on the contrary, in an oblique line, without any interruption, the diforder rapidly fpreads through its whole extent. It would be polfible, in order to derive every advantage from this mancesure, to augment confiderably the fire of the firl eckellon, as well as the one immediately fublequent, by doubling their lines, and leaving the others weaker. Hence it is evident, that this mode of attack is eligible only when we are a head of an enemy ftronger than ourlelyes; for if we have a fuperior force, it is certain that the moft energetic method would be to attack at once the adverfary in front and both flanks.

There is fcarcely an infance previous to the battle of Marengo, in which a fecond line of infantry has renewed the combat, by taking the place of the firt which has been beaten. If the combat be continued with
bayonets, it would be fufficient for a divifion of the line AB to make a converfion on the flank of the ćchellon \(c d\), while they are fighting in front, and overthrow it before ef, 300 paces diftant, or even the fecond line of the echellon, could come up to afford it any afliftance. Thus, according to all appearances, the line AB would conquer all the échellons fuccelfively, and this the more eafily as they would be taken in flank as foon as \(c d\) is obliged to Hy.

The molt ufeful, and in fact the only procefs for reinforcing an attack, is to have a fecond line of cavalry behind a firlt of infantry; in cafe of bad fuccefs they fecure and cover their retreat, and complete the diforder of the enemy's infantry, if they come to an engagement.
When the infantry is ranged en echiquier, a firft line when beaten, may retreat by files through the lines in the rear, without creating any dilorder in the fecond, on account of the extenive lpaces; but it is not the fame with the long phalanx in open order. The cavalsy, placed immediately behind the infantry, protects an attack much better than if these were between them a fecond line of infantry; for in the firlt inftance, there would be no hindrance to their haftenity to the fuccour of the runaways, and receiving them in their bolom. Hence there floould be only two lines, one of infantry, and one of cavalry; and this is the more important, becaufe the two lines of infantry cannot be ufeful, except in as far as thiey ate beyond the fhot of the cannon; it is evident, therefore, that they flould be confidered rather as a referve of frem troops than as a fecond line of combatants. Hence, the fupperadded ftrength which is fuppofed to be given to the échellons, by double lines of infantry, is quite iilufory.

Cannons which fire concentrically, affift greatly the efficacy of an attack; but this meafure may be employed as well for right lines as for the échellons; in an attack of the latter kind, the batteries thould not be plaeed before the divifion \(c d\), but before eff, to enfilade that part of the line \(A B\), which would attempt to fall back to make a converfion, i: cafe it were attacked in flank by cd.

It is impolfible to take the enemy in flank by the diagonal or fide-ftep, executed during the march, if, previous to commencing their march, they are not already confiderably by their wings; for they would completely fruftrate that fcheme, if they made directly with their flanks a movement to the fide. During the fame time they would pafs over a more confiderable extent of ground than with an oblique ftep, becaufe they move in a direet line, and in front, and obliquely, both at the fame time, which would confiderably llorten their diftance; and likewife becaufe they march on one of the fides and you on the hypothenufe, which is longer. It is therefore impoffible to fucceed in ftretching beyond the wings of the enemy, while they are advancing in front in the order of battle, if they know how to conduet themfelves.

There is, however, one advantage to be noticed, which the ichellons polieds over the uninterrupted oblique front, which is, not expofing the flank to the encmy advancing in front. The cichellons naturally poffefs this adrantage, while the oblique front cannot obtain it withont bcing mucli more exterfive than the enemy's front; for the oblique line, formed into cchellon.,
changes into a number of parallel lines by a converfion (fig. 38.), and they may, by this movement, defend their tlanks againft the enemy. But ftill the beft way is to attack him in his own flanks, whillt his front is araufed with detached corps, and the columns fhould be prepared for the principal attack out of fight of the eneny, in the fame manner as an admiral adopts at a confiderable dillance, his neeafures for gaining the windward of the enemy. No manoeuvres within cannonflot, can poffibly be attended with fuccefo, if the enemy be ikilful.

Much ufeful military inftruction may be derived from Lift of reperufing the accounts of the moft celebrated battles, de-markable tailed by writers of ancient and modern hiffory; and baules. we could here enumerate a long lift of thefe engagements, many of which have been defrribed in the hiiftorical articles of this work. A few, however, muft fuffice. Of ancient battles we may notice thofe of Marathos * in 490 B. C.; Platea, 479; Leuctra* , See tbefe 371 ; the Granicus*, 334; Arbela*, 331; thearticles. Thralymene Lake \(\dagger, 217\); Canne*, 216 ; Zama *, thee Car202; Magnefia \(\ddagger\), 190; Nepheris, i47; Pharsalian , thage, \(\mathrm{NO}^{2}\) 48; and Phlifpl \({ }^{*}, 4^{2}\). Of modern battles, the moft \(\ddagger\) See Syrio. important are thofe of Hastings *, A. D. ro66; the \|f See Garo Indus ||, J 221 ; Bannockburn §, 1314 ; Crlssy*, 1346; na.  and more fully explaining what has been faid on the 414 . order of battle, we fhall here give a detail of the battle ill See of Jemappes, in which Dumourier entirely defeated Prufia, General Clairfayt, by enticing him from a fituation \(\mathrm{N}^{\mathrm{O}}{ }^{26,35^{\prime}}\) where he was impregnable.

Battle of
In the beginning of Norember 1592, when Dumou-Jemappes. rier arrived with his army in the vicinity of Mons, he found the Auftrian general Clairfayt occupying a ftrong pofition on the heights near the village of Jemappes, where he had entrenched himfelf, and was defended by nearly 100 pieces of cannon. The pofition of the Auftians was extremely formidable. Their right extended to the village of Jemappes, and formed a fquare with their front and left, which ftretched to the caufeway of Valenciennes. They were polted on a woody mountain, where they had erected, in an amphitheatre, three ticrs of redoubts. Their whole force amounted to about 16,000 infantry, and 3000 cavaliy.

The army of Dunourier was much more numerous than that of Clairfayt, but not fo well fupplied with artillery. The elcration of the Auftrian batteries, too, gave them fuch an advantage, that the French cannon could produce but little effect.

On the 5 th of November, Dumouricr had fully reconnoitred the Auftrian camp, and, by way of feint, made an attack with his infantry on the village of Carrignon, while he kept up a brifk cannonade on their left. 'Towards evening the French army cucamped oppofite to Jemappes, with its left wing extending to Hoorne, and its right to Fremery. As Dumounier refolved mappes the next morning, he ordered his troops to abandon the village of Carrignon, which was commanded by the enemy's cannon.

On the morning of the 6th, he ordered his artillery to be advanced and difpofed along the front of the line. It was foon fuund, however, that little was to be done with artillery, and that the great objeet was, to entice the Auftrian general from his ftrong polition, and draw bim to the plain. For this purpole, at noon of the 6th, the French infantry formed in columns, and advanced with the greatef fpirit and rapidity to the Aullrian intrenchments. The lower tier of redoubts was inftantly carried; but, as the centre of the French became endangered, and the Aufirian cavalry appeared defeending from the heights, and preparing to enter the plain, with an evident intention of flanking the French columns, Dumourier defpatched the duke of Orleans to lead thofe columns againft the fecond tier of redoubts, while a detachment of chaffeurs and huffars llew to check the progrefs of the Auftrian cavalry. Some fmart flkirmifhing between the cavalry on both fides now enfued, and while this diverfion was taking place, the left divifion of the French army poffeffed themfelves of the village of Jemappes, while its centre obtained entire poffeftion of the fecond tier of redoubts. In the mean time the whole of the Auftrian cavalry had quitted the heights, and engaged the French on the plain below Jemappes. This was the point to which Dumourier had wilhed to bring them, and now the fuperior numbers and activity of the French quickly decided the fortune of the day. The Auftrians were routed at every point, and forced to abandon the field of battle, leaving 5000 of their dead, with the greater part of their artillery. The lofs of the French, however, was confiderably greater, and is, on good authority, etlimated at 14,000 ; but this lofs appeared trifing to Dumourier, as by this victory he acquired poffeffion of the whole of the Auftrian Netherlands.

The pofitions of the French and Auftrian forces in this battle are reprefented in Plate DLIV. J, The centre of the Auftrian army, commanded by Clairfayt. 2, A part of this army commanded by General Lilien. 3, A nother part under the command of General Beaulieu. . 4, Redoubts on the heights of Jemappes. 5, Auflrian intrenchments. 6, French columns advancing to attack the intrenchments. 7, A battery. 8, Columns of cavalry. 9, Columns attacking the eminences abuve Mons. IO, Battery on the height of Fremery. II, The wood of Frefnce. 12, The plain on which the French and Auftrian cavalry were engaged. 13, Auitrian detachment.

The columns \(\mathrm{N}^{\circ} 9\). were frlt engaged; and \(\mathrm{N}^{0} 6\). having obtained fome advantage, Dumourier ondercd the battery, \(\mathrm{N}^{0} 7\). to be erected, by which the redoubts, \(\mathrm{N}^{0}\) t. were filenced. In the mean time the French adranced againft the intrenchments, 5, and attacked in front. From the left of the French army, as far as the centre, the cavalry fought hand to hand, in the plain, 12, with the Auffian horfe, which was dread fully cut up in the wood of Du Frefnee, II. The right of the Aultrians, being totally routed, gave way and fell back on Mons. The luperiority of the French in numbers is evident from infpecting the columns in the plan.

After having divelt fo long on that part of military
tactics which relates to operations in thee field, we muft Military be extremely brief with relpect to the attack and de- Tactics. fence of fortified towns. Indeed our principal object in 43 this part will be to explain the nature of a fiege, and of fieges. the various circumilances that may occur, both on the part of the befiegers, and on that of the befieged, rather than to lay down a fyftem of inftuctions for either party. With this view, we flall firf enumerate the principal influmetuts and engines employed in the attack or defence of a fortrefs, and explain the nature and conftruction of the works conltructed by the befiegers, either for the purpofe of making their approaches to the place, or for undermining its walls or outworks.

In Plate DLV. are reprefented the principal influ- Infruments ments employed in fieges. Fig. 1. is a fafcine for the employed conftruction of redoubts or temporary defence of a de- Matese tachment. Figs. 2.3. and 4. exhibit various views of DLV. what are called gabions, or cylindrical cafes of wicker Fig. 1-20. work, open at both ends, for Iticking into the ground, as feen at fig. 4. when they are lilled with earth, and fafcines, \&c. laid on them. Fig. 2. is a fection of the gabion; fig. 3. ीhews its hollow infide, and fig. 4. is its elevation. Fig. 5. and 6. reprefent bags for holding fand, the former empty, the latter full; and fig. 7. reprefents the manner in which they are ufually dilpofed for the protection of the men. Fig. 8. is a fauciflon, or very long clofe faggot, for laying over gabions. Fig. 9. is the outline of a blind, which is fluck into the earth by the fharp fakes at its extremity, and hides the workmen from the befieged. Fig. 10. reprefents what is called a chandelicr, and fig. I1. two of thefe with fafcines piled up acrofs them. Fig. 12. is a cheval de frize; fig. 13. 14. 15. exhibit various views of a mantlet, or moveable blind placed on two wheels, ufed both to protect and conccal the workmen of the befiegers. Fig. 13. is a plan of the mantlet; fig. 14. a fide view of it, and fig. 15. a view of its front next the enemy. Fig. 16. is a madrier or fcreen with two leaves, moveable on wheels; and fig. 17. reprefents a gate wilh orgues or lattice work on one fide, and a portcullis on the other. Fig. 18. is a hook, and fig. 19. a fork nfed in fapping. Fig. 20. reprefents three caltrops or crows feet, uled to fcatter over the ground, to prevent the approach of cavalty, by laming their horfes fect. For a fuller explanation of thefe iaftruments, fee the feveral articles in the general alphabet.

When a town is about to be befieged, it is firf imed-of inveted; that is, a confiderable body of troops, ufually ca-ing. valry, cncamp in its neighbourhood, and take poffiffion of all the avenues till the army arrive, which is to carry on the regular operations of the frege.

When the army has faz down before the place, its of lines of firt object is, to afcertain the lines or direction of the circumval works to be thrown up for the attack of the place. Thefe are called lines of circumvallation, and their direction is to be determined by the plan of the fortification about to be befieged. Aficr afcertaining, in the manner explained under Fortification, the number of fides of which the polygon of the place confifts, and the length of each, as well as the radius of a circle to be drawn round the place, concentric with its works, the polygon of the circumrallation is eafily defcribed. This being traced, the engineer takes on each of the extremities of its fides the lines \(B D\) and \(B E\), fig. \(2 I\). each of 15 fathoms, and from the poinis \(D\) and \(E\),
laken for the centre and ditance of 2 f fathoms, te defcribes two arcs cutting each other at \(F\), whence are drawn the lines FD, FE, for the faces of the redans of the line of circumvallation; thus are formed the falient parts EFD of this line, which ferve to flank it. The fame operation is performed on every fide of the circumvallation, and then the principal line is traced. The parapet within mult be fix or eight feet deep, and without is made a ditch parallel to all its parts, three or four fathoms in breadth. The parapet of the circumvallation will be \(7^{\frac{1}{2}}\) feet high, and the depth of the ditch equal to the height of the parapet.

To make the profile of the circumvallation, let AB , fig. 22. be a line level with the country, and CD the fcale of the profile. Let \(A\) be the ficle of the town, and \(B\) that of the country; talke \(A E\) of fix feet; from the point E , raife the perpendicular EF, of three feet, and draw the line AF, which will be the talus or flope of the banquette.

Draw FG parallel to \(A B\), three feet from \(F\) to \(G\), and the line FG will be the breadth of the banquette. On the point G raife the perpendicular GH , on the line FG, \(4 \frac{T}{\gtrless}\) feet. Draw from the point H, HK parallel 10 AB ; make \(\mathrm{HK} 7_{\frac{1}{2}}^{2}\) feet, HI , \(1 \frac{7}{2}\) foot ; draw Gl, which will be the infide of the parapet of circumvallation.

From the point \(K\), let fall on the line \(A B\) the perpendicular KM; take KL \(\frac{1}{\frac{T}{4}}\) foot, and draw IL, which will be the upper part of the parapet of the line of circumvallation. Take MN equal to five feet, and from the point N draw the perpendicular NO , and fet off \(7 \frac{1}{\frac{1}{4}}\) feet from N to O . Draw OR parallel to AB , making the diftance equal to 18 feet from \(O\) to \(R\); drave LN, and produce it to P, and LP will be the fcarp. From the point R raife RS, perpendicular to OR , or parallel to \(O N\). Make \(\Omega R=O P\), and draw \(Q S\), which produce beyond S , thrce teet to V ; then take SX equal to fix feet, and draw VX, and the profile of the circumvallation is completed; VQ being the counterfcarp, and VX the glacis.

At A and A (fig. 21.) are fmall half moons before the gates of the circumvallation in the middle of the curtains.

In Plate DLVI. at fig. 1 . is reprefented the manner in which the lines of circumvallation were drawn at the fiege of Philipfburg in \(1 \% 34\). In thefe lines regular baftions were coniftucted, as feen in fig. 2.

Plate

Fig. 4. and 5 . of the fame plate reprefent another line of circumvallation drawn round the city of Arras, when it was befieged by the Spaniards in 1654 . Before the circumvallation were dug a great number of holes, two feet in diameter, and \(1^{\frac{7}{2}}\) foot deep, in which were faftened Atakes for obffructing the approach of cavalry.

While the lines of circumvaltation, which are intended to proted the beffegers from the enemy without, are conftruted, all materials neceffiry for the trenches are got ready, and the figure and direction of thefe are determined. If the place be regularly fortified, and ftand on level ground, it is indifferent on which fide the befiegers commence their attack. Suppofo C, fig. 2. Plate DLN'II. to be the place befieged, and A and B two baftions to be attacked. The befiegers begin with indefinitely producing towards the field the capitals of thefe two baftions; in like manner the capital of the half moon oppofite the curtain between thefc two ba-
ftions is produed. Eight hundred fathoms ars fet off from the falient angles D ) and E of the covert-way of F and G. This done, the lines DH and DI are drawn, each equal to 300 fathoms, and about the centre C with the radius CH or CI , is deferibed an arch produced beyond H and I , and on this arch HI is conllructed the firft parallel. Then on the fame lines DI, EG, are taken the points \(M\) and \(N\), each 140 fathoms difant from H and I; and through thefe points M and N , about the centre C , is defcribed another arch, on which is conftructed the fecond parallel. This fecond arch will cut the produced capital of the half-moon in the point L, which is to be obferved, in order to begin from hence a trench which may extend to the falient angle of the covcrt-way before this half-moon. Laftly, through the points \(O\) and \(P\), the diftance of 20 or 23 fathoms from the angles \(D\) and \(E\), a third arch is defrribed from the centre C , on which the third parallel is contructed. The firt parallel is terminated by producing the faces \(a b, a b\), of the half-moons 1 and 2 , collateral to the battions \(A\) and \(B\); but the parallel is extended 15 or 20 fathoms beyond the interfection of this prolongation. The fecond parallel will be lefs extended than the firt, by about 30 fathoms on each fide, and the third lefs than the fecond by the fame diflance.

The trenches or approaches are now to be traced. For this purpole, the engincer takes a long ruler, and lays it on the point \(G\), fo that it may make with the produced capital EG of the baftion B, an angle EGS, whole fide GS being produced, thall meet no part of the covert-way, and thall be diftant about 10 or 12 fa thoms from the angles to which it approaches nearef. GS is taken of any extent, and the ruler is put on the point S; fo that it hall make with GS fuch an angle GSI', as that the fide SI' produced fhall not fall on any part of the covert-way, but be 10 or 12 fathoms diftant from the mof falient parts. This fide is terminated in I ; and now the angle STI is made, whofe fide Tl fhould terminate at the foint \(I\), where it meets the firt parallel. The fame opcration being performed on FH, the outline of the trenches is completed as far as the firft parallel.

Fig. 1. of this plate illuhrates the method of confructing what are called lines of countersallation. Thefe are drawn nearer the town than the lines of circumpallation, but are conftrcted on the fame principles. They are employed chittly when the garrifon of the place is fo ftrong as to difturb the operations of the befieging army by fallies.

In lieges where the garrifon is frong, it is often neceflary to cut parts of trenches, as VV (fig. 2). between the fecond and third parallels, fo as to communicate with the main trench. Thefe parts of parallels are denominated half parallels, or places of arms, and are conftructed in the following manner. Let ABCDFGMiQ (fig. i. Plate DLVIII.) be a part of the trenches, and let \(A B\) be one of the fides oppofite to the enemy; produce \(A B\), fo that BE flall be five or fix fathoms, and in FG take alfo five or fix fathoms from 1 to L , which will give the ands of the trench 3IFL.I, the ufe of which is to cover the loyace or branch IOMCs, whereby the encmy will not know the place wiere it falls into the trach AB , and to make room for v ithdrawing thole who are in this part of the trench-
liltary es, and that the paffage may be frce at all the angles. In like maner produce the fide G.M from MI to N , and the fide IC from O to P , and this will give the end of the trench MNUP, which will cover the branch \(\mathrm{D}=\mathrm{O}\) ). The fame is to be done at all the angles of the trench. The parapet of the trench being made to cover it, ought to change fides alternately. If, for inftance, AE, in the preceding figure, be towards the plice, it is evident that the fide CiN wilt be towards it alfo, and likewife the fide CD ; and therefore the parapet of the trench is fuccefii: ely conitiucted from the right fide to the left, and tom the lett to the right.

Fig. 2. 3. 4. of this plate reprefent profics of ti.e re gular trenches and the places of arms, and require no particular explanation.
In tracing the trenches, it is of the greate:t confequence to alcertain the ditance of the extremity of the line of diection to the top of the falient angle of the covert-way. The folloring finple method of duing Fis. 5. this is given by Vau'an. Let \(\Lambda\) (fig. 5.) be the vertex of the falient angle of the covert-way, and AB the line of diredtion of the trench whofe Iength is required. At the point B, draw BC perpendicular to AB, to which give any meafure, and at the point C draw CD ) perpendicuiar to BC In CD take any point E , and in the line of direction between it and the angle A place a picquet \(G\) in the line BC . Meafure GC and CE, and fay, as GC: BG:: CE: AB.
When in carrying on the trenches towards the town, the workmen begin to be much annoyed by the fire of the hefiegod, recourfe is had to what is called fapping, lefs the men have fome cover againft the fire of the place; and let the branch \(A D\) be traced by the engineer, not with a cord, as at the opening of the trenches, but with fome pickets, which he has taken care to place in the direction this branch ought to have, to ferse as a guide to the workmen. A cut is made in the parapet \(B A\) of the trenches, and then the men defigned to work by fap, who are therefore called fappers, will move fornard through the opening A fucceflively, eight in number. Fig. 7. of Plate DLVIII, and fig. 1. of Plate DLIX. will illuffrate the mode of operation. The firt fapper rolls a mantlet before him, and places a gabion on the line AD. fig. 6. He then makes a fmall excavation about fix inches from the gabion, of about one foot and a half in depth, and as much in breadth, emptying the earth which he digs up into the gabion. He then pufhes forward his mantlet, fixes another gabion. and continues his trench as lone as he is able. He is followed by a fecond, who widens the trench fix inches in breadth away from the gahion, and fix in depth. The reft follow this fecond, till the trench is made three feet wide, and as many deep, and as foon as the gabions are filled with earth, fafcines or fauciffons are placed on their ton, and the finerflunus earth is thrown over them, and on the oppofite fide, by way of parapet.

Carnon are made ufe of at a fiege for two diferent purpofes; the firt to drive away the enemy from their defences, and the fecond to difmount their cunc. To produce thefe two effects, the batteries fhould not te
above the mean reach of cannon-fiot from the place; that is, above 300 fathoms. I heret ,re there i, no pollivility of contructing then till the firt paraliel be formed; and as the dutance of this firft pasallel from the place is generally \(3=0\) fathoms, the batteries anulk ue on this line, or beyond it, nearer the town. They mult always be placed, when the ground will permit, on the produced faces of the work attacked. leet \(Z\) be the centre of the place attacked (fig. 3. Plate D1.1X), and the trenches as well as the parallels completed. 'To find a proper pofition for erecting batteries, produce the faces \(\mathrm{AD}, \mathrm{AC}, \mathrm{BE}, \mathrm{BF}\), of the two bafions attacled, till their prolungation cuts the fint parallel. Produce alfo the two faces OM and OL of the hat -muon MOL of the front attacked, and the laces IGG and IK of the two collateral halif-moons 1 ard 2 , to the frif parallel, and erect batteries on thofe produced faces, as is feen in \(\mathrm{J}, \mathrm{Q}, \mathrm{R}, \mathrm{S}, \mathrm{T}, \mathrm{U}, \mathrm{X}\), and Y '. They are advanced beyond the firf parailel 40 or 50 fathoms; and are pated from the trenches, that they may be uled with greater eafe and convenience, and le!s trouble to the workmen.

When the works of the befiegers approach the glacis, of trd- 5 . they are continued in a zis-zag direction, by flout an-vertes gular trenches, but from the foot of the glacis they are continued in the following manner. Two fets of Cappers, protected by their mantiets, make a lap on each fide of the ridge of the glacis, with a deeper ditch than ufual, and a parapet on each fide. This is called a double fap, and has acrofs it traverles or banks three fathoms thick (fee Piate DLX. fig. 1.), with fmill paffages on one ficle (fee fig. 4.) to preferve the communication. Thefe traverfes are conftrufed fo near to each other, as to te a fufficient cover, by their elevation and diftance, againft the fire of the place. In order to guard againit the effect of grenades, on coming within their reach, or within 14 or 15 fathoms of the covert-way, care mult be taken to cover this trench with blinds, or to cover the upper part of it. Fig. 1. and 2. of Plate DLX. fhew this direct trench. The firll exhibits the plan, and the fecond the profile, which paffes over cne of the traverfes. 'This being done, and the third parallel finifhed in the manner fuppofed, tley advance from this parallel on the glacis to each of the falient angles of the covert-way of the front attacked, and berin with making two or three thurt turaings, as marked on Plate DLX. fig. 6. along the ridge of the glacis, fo as to occupy about one-third of it. Thefe are to be made as deep as is neceeflary. to be a Melter againft the fire of the covert-way ; atterwards they may proceed directly along the ridge of the glacis by a deep ditch, to the falient angle of the covert-way. M. Vauban obferves. that if we follow directly the ridge of the glacis, this trencls is made without much danger; for the palifade which is placed at the falient anghe of the envert-way, and the other two next it, do not prefent directly to the ridge, but only oppofite to the face:, where at moft there is only room for one or two fuff. leers in fee the head of the trenches, and who are eafily filenced by the fire of the third parallel, which oucht to be well ferved, and likewife by that of the ricocet. O. coming to the middle, or twn-hirds of the glacis, two new faps are made, \(b b\), ibid. which emhrace be \(h\) fides of the covert-way, io which thev are almon parntlel. Their length is 18 or 20 fathoms, and abuer five bruad.

Of batteries on the covertway.

Plate
DLX.

Fig. 6.
winding traverfes, which prevent the fire of the covertway from enflading them eafily.

In this way is gradually effected a lodyement on the covert-way, as is reprelented in fig. 5. where AAAA, is the trench, with BBBB its traverles.

Plate DLXI. fig. 5 . reprefents a profile of thefe works, with three banquettes next the trench, by which the parapet is raifed, to that the foldiers may fire over into the covert-way. This work is called by Vauban, the cavallier of the trench.

When the befieged are entirely driven out of the co-vert-way, the next thing to be done is the erecting of batteries, in order to ruin the defences of the place, and to make a breach. As it is neceffary for the befiegers to make themfelves matters of the half-moon C , (Plate DLX. fig. 6.) before they can come to the body of the place, which is defended by part of the faces of the baf- tions \(A\) and \(B\) oppofite to its ditch, they muft begin with erecting batteries on the covert-way oppolite to thele parts. They are marked on the plan ee. Batteries mult alfo be erected to make a breach on the half-moon. But, before they are erected, it will be proper to confider what part of the lace of the half-moon is to be attacked, or what part of the half-moon is to be entered. It muft not be at its flanked angle, becaufe an opening towards the point would not afford a fufficient fpace to make a lodgement able to withftand the enemy, and the troops would be feen, in their paffage by the two faces of the baltions by which its flanked angle is defended. The mof favourable paffage is towards the third part of its face, reckoning from its flanked angle, becaufe by battering at the fame time the two faces near this part, the whole point of the half-moon may be deftroyed, and a large opening made there eafier than anywhere elfe. Thus the batteries for making a breach in the half-moon \(C\) will be placed \(i, 1 d\) and \(b\), and will occupy almolt one-third of each of the faces of the half-moon from its flanked angle. Thefe batteries are each to confif of four or five pieces of cannon. When the faces of the batlions \(A\) and \(B\) are well enfiladed by ricocliet batteries, there will be no further occafion for the batteries \(c, e\), and when the half-moon is taken, the faces of tbe baftions A and B may be deftroyed, by ufing the batteries \(d_{2} d\), placing them in the fituation of \(e, e\). Batteries mult alfo be crected io deftroy the flanks of the demibaftions in the front of the attack; and it is evident that they can be placed nowhere but at \(i, i\), on the co-vert-way. Befides thefe batteries, others are erected in the re-entering places of arms of the covert-way, as in \(k\); and in \(k\) they ferve to batter the tenaille when there is one, the curtain, and the faces of the baftions. Sometimes they are of mortars for throwing ftones.
Defcent While the workmen are employed in erecting batand paffage teries on the covert way, preparations are made for pafover the fing the ditch of the half moon. "Ihis is often a diffiditcli of the cult and dangerous undertaking, as this ditch is com-
monly very deep, is well defended, and either filled with water, or in general capable of being fo filled. The defent into the ditch is commonly effected by fubterrancous paffaytes or galleries, made like thofe of miners, and crected in fuch a manner, that its opening into the ditch may be oppofite to the breach where it is intended to make the aflault. Thefe galleries are floping,
and in general there are feveral for the fanse paffage. The pallage is made on each fide of the faces of the half moon. See \(m \mathrm{~m}\), fig. 6. Plate DLXI.

As the bufinels of forming thefe galleries is liable to Le obllructed by mines from the befieged, the workmen are protected by a guard of grenadiers. At fig. 1. Plate DLXI, is feen a plan of the defcent under ground, and of its opening into the dry ditch; and fig. 2. gives a profle of the fame paffage; fig. 3. gives a perfpective view of the opening of this delcent, feen from the bottom of the glacis, and fig. 4. a fimilar view of the opening of the fime defcent, feen from the top of the breach.

At Plate DI.XII. Gg. 1. is feen the plan of the pafo fage over a wet ditch in the open air; that is to fay, the gallery of which is an open fap. \(A\) is the opening of it; at \(B\), towards its opening, are feen the blinds laid on its upper part, to fupport the fafcines with which it is covered. On thefe blinds, at firft, is laid a bed of fafcines, ranged according to the length of the gallery: over this firft bed a fecond is laid, whereon the fafcines are ranged according to the breadtl of the gallery, as is feen at B and C. D is the epaulement of fafcines, which covers the paftage againt the fire of the place by which it is flanked. E is part of the bridge of fafcines; and F is ats elevation alfo of fafcines, intended to cover the head of the work, and to fecure it from the immediate fire of the place. Fig. 2. reprefents the profile of this defcent into the ditch. Fig. 3. gives its opening feen in perfpective from the country; and fig. 4 . its opening into the ditch, alfo in perfpective, as it appears from the top of the breach.

The following references will explain fig. 5. of Plate DLXII. \(a\), eavaliers of the trenches. \(b\), batteries of ftone mortars. \(c\), batteries to breach the half moon before the hornwork. \(d\), batteries againt the defence of this half moon. e, paffages over the ditch before this half moon. \(f\), lodgements in it. \(g\), batteries againft the flanks of the hornwork. \(h\), batteries to breach the half baftions of the hornwork. \(i\), batteries againft its curtain. \(l\), lodgements in the half baftions, and in the hornwork, \(m\), paffages over the ditch before the retrenchments in the hornwork. \(n\), lodgements in thefe retrenchments. \(O\), batteries againft the defences of the collateral half moons. \(p\), batteries to breach thofe half half moons. \(q\), paffages over the ditch before thefe works. \(r\), lodgements in the fame. \(s\), batteries to breach the redoubts of the half moon. \(t\), paffages over the ditch before the redoubts. \(u\), lodgements in the redoubts. \(x\), bridge of fafcines. \(y\), batteries againn the defences of the baftion A. \(z\), batteries to breach this baltion. B, paflages over its ditch. C, lodgements in the baftion A. D, lodgements on the border of the dith before the retrenchment of the baftion \(A\). \(E\), paffages over the ditch before this retrenchment.

There are places which, without any fore-ditch, have lunettes oppofite to the falient and re-entering angles of the glacis, which are alfo enveloped by a fecond covertway: fometimes they are vaulted and bomb-proof, as at Luxemburg; and fometimes they have only a ditch, a parapet, and covert-way. Thofe which are vaulted and bomb-proof are not eafily taken, becaufe the ricochet firing and the bombs can do them no milchief. In that cale they muft either be turned, or be taken by mines. A work is faid to be turned, when the befie-

Multaty gers get between that work and the place, and fo cut TaCtics. off their communication. Sometimes the lunettes have communication under ground, and then there is fcarcely any other way of driving out the encmy but by mines. This is tedious, but there is no other remedy. The lunettes of the ditch are always delended by branches of the covert-way, with which they have allo a communication like thofe of the lunettes, \(A, A\), Plate

Plate DLXIII. fig. r. This plate, which reprefents part of Landau and its attacks in 1713, may ferve to give an idea of the manner in which a work is turnchl. The advanced lunette \(B\), as weil as the work \(C\), called a tenaille, is turned ; that is, the trenches cut off the communication betwixt them and the place.

We fhall conclude this fubject of the attack of fortified places, with the following principles to be obferved by the befieging army.

The approaches onght to be made, without being feen from the town, sither diredty, obliquely, or in flank.

No more works thould be made than are necellaty for approaching the place without being feen; that is, the befiegers ought to carry on their approaches the fhorteft way pofliole, confiftently with being covered againft the enemy's fire.

All the parts of the trenches fhould mutually fupport each other, and thofe which are furtheit advanced ought not to be diftant from thofe which are to defend them above 120 or 130 fathoms.

The parallels or places of arms the moft diftant from the town, ought to have a greater extent than thole which are neareft, that the befiegers may be able to take the enemy in flank, fhould they refolve to attack the neareft parallels.

The trench fhould be opened or begun as near as pofGible to the place, without expofing the troops 100 much, in order to accelerate and diminilh the operations of the fiege.

There is no fuch thing as giving any exact rule in regard to the diftance which ought to be obferved on opening the trenches. On level ground, this diftance may be 800 or 900 fathoms; but if there fhould be a hollow way in the vicinity of the place, the befiegers are to take advantage of it , and open the trenches nearer. In general, they are to regulate them'elves according to the nature of the ground, more or lefs fa. vourable to the opening of the trenches. We fhall fuppole in the prefent work, that the opening ought to be made within 800 fathoms of the covert way; the firft parallel within 300 fathoms, the fecond within 150 , and the third at the foot of the glacis.

Care muft be taken to join the attacks, that they may be able to fupport each other.

Never to advance a work unlefs it he well fupported; and for this reafon, in the interval between the fecond and third places of arms, the befiegers fhould make, on both fides of the trenches, fmaller places of arms, ex-
tending 40 or 50 fathoms in length, parallel to the others, and conllructed in the fame manmer, which will ferve to lodge the foldiers who are to protect the works defigned to reach the third place of arms.

The batteries of cannon nult be placed in the continuations of the faces of the pieces attacked, to filence their fire, and that the approaches being protected, may advance with greater fafety and expedition.

For this reafon the beliegers flould always embrace the whole front attacked, to have as much pace as is requifite to plant the batteries on the produced faces of the works attacked.

The attack muft not be commenced witlo works that lie clofe to each other, or with re-entrant angles, which would expole the attack to the crofs lire of the enemy.
Many circumflances refpecting the defence of forti-General refied towns have already been anticipated, or may be marks on collected from what has been faid refpecting the opera- of fortiticed tions of the befieging army. It is evident that the fuc- towns. cefs or duration of the defence will depend in a great meafure on the nature and frength of the worls which form the fortification. Much, however, will allo depend on the number, refolution, aid refources of the gatrifon, and on the movements of the friendly army by whieli the befiegers may be oppofed. It is eftimated by M. Vauban, that the operations for a regular fiege of a well fortified town, will take up about 41 days, before the place can be carried by affault. Hence is deduced a computation of the quantity of provifions, ammunition, and ftores which ought to be collected for maintaining the fiege. The fame celebrated engineer calculates that the garrifon ought to confifi of 600 times as many men as there are ballions in the fortifica. tion, allowing 600 men to each battion. Befides the neceffary defence of the works by the cannom on the ramparts, and the mufketry of the foldiers, the garrifon mutt make occafional fallies; if weak, to difurb the operations of the befiegers, and if very ftrong, to engage them in the field. As the ficge advances, and the attacking army approaches the glacis, mines thould be fprung, and fubterraneous paffages excavated, to deftroy the enemy's works, or cut off a part of their men.

Towards fupplying the unavoidable deficiencies in Reference the above 作etch of military tactics, we may refer our to authors readers to Clairac's Field Fingineer, iranflated by Mul- on military ler; Le Cointe, Science des Pofes Militaires, or the \({ }^{\text {tactics. }}\) Englifh tranflation; Jency's work entitled Le Partifan, alfo tranflated into Englifh; O'Rourke's Trentife on the Art of War; Effai General de Tactique; Tielke on the Art of War, and his Field Engineer; Dundas's Principles of Military Movements; Landmann's Elements of Tactics: Maizeroy's Syfteme de Tactique; Archives Militaires; Feuquiere's Menoires; Bland on Military Difcipline; Military Inflructions for Officers dctached in the field; and the articles Battalion and Battle in Iees's Cyclopadia.

\section*{PART II. NAVAL TACTICS.}

BY naval taclics is underfood the art of arranging fieets or fquadrons in fuch an ordes or difpofition as may be moft convenient for attaching the enemy, defending Tol. XX. Part II.
themfelves, or of retreating with the greatef advantage. Naval tactics are founded on thofe principles which time and experience have enabled us to deduce
from the improved fate of modern naval warfare, which has occafioned, not only a difference in the mode of conltructing and working hlips, but even in in the total difpofition and regulation of fleets and fquadrons.

In the prefent part we propofe to lay down the general principles of naval tactics, and to defcribe as briefly as is confiltent with perficuity, the moft improved fyltems which are now adopted in the French and Britifh navy. As we have elfewhere (fee NaviGatron and Seamansilip) detailed the methods of working fingle hips, as they are unconnected with military operations, we hall prefume that our readers are already acquainted with thefe ordmary movements.

Fleets are generally divided into three fquadrons, the van, centic, and rear, each under the command of a lagg officer. The admiral of the fleet, or chicf in command, leads the centre divifion, while the van is ufually commanded by a vice-admiral, and the rear by a rear-admiral. Each fquadron is dittinguilhed by the pafition of the colours in the Mips of which it is compored. Thus, the fhips of the centre fquadron carry their pendants at the nain-top-gallant mati-head; whle thole of the van divifion have their pendants at the fore-top-gallant mafthead, and thofe of the rear at the mizen-top-mafthead. Each fquadron, as far as poffible, confits of the fame number of flips, and as nearly as may be of the farne force. In large fleets, the fquadrons are fometimes again divided in a fimilar manner; the van and rear of the fquadron being lieaded by rear-admirals, or fenior captains, called commodores. In the ufual mode of forming the lines, each commanding admiral arranges his fhip in the centre of his own fquadron, and thus the admiral of the fleet is in the centre of the line. When no enemy is in fight, the floops, fore-flips, fire-flips, and other fmall veffels, are difperfed to windward of the fieet, that they may be more cafly fuppoited, and more readily anfwer fignals. The frigates lie to windward of the van and rear of the convoy, thus keeping a gand look-out, and keping the frall veflels in their proper ftation. When failing in three colunns, the centre tall heeps in the raiddle, while the van and rear form the ftarboard or the larboard column, according to circumftances. Thefe arrangements are called orders of failing, and will be better underflood from the following definitions.

The flarboard line of bearing, is that line on which the arranged fhips of a flee: bear from each othcr, on a clofe hauled line, whatever courfe they may be fteering, fo that when the fhips haul their wind, or tack logether, they may be on a line clofe hauled upon the ftarboard tack. The larboard line of bearing is that line on which the fhips when hauling their wind, or tacking together, may be formed on a line clofe hauled on the larboard tack. The fhips of a fleet are faid to be on a line abreal, when their keels are parallel to each other, and their mainmafts lie in the fame ftraight line. Ships are faid to lie in a line on the bow or quarter, when they are arranged in a ftraight line, cutting their keels obliquely in the fame angle, fo that reckoning from any intermediate flip, the flips towards one extiemity of the line will be on the bow of that thip, while there towads the other extremity will be on her quarter. When feveral hips in the fame line fleer the fame
courfe, while that courfe is difficont from the line of failing, they are faid to fail checquernife.

When the fhips of a ficet arranged in any of the orders of failing, and on the fame line, perform fucceflively the fame ma:couvre, as each gets into the wake of the thip that leads the van of the line or fquadron, tacking or veering, bearing away or coming to the wind in the fame point of the wake of the leading hip, they are faid to mancuvre in fuccelion.
'There are uftally rectioned five orders of failing; ex- Intitatio clufive of the line of batlle, the order of retreat, \&c. of the live In the firl order (fee Plate DLXIV. fig. 1. and 2.) the orders of fleet is arranged on the Aarboard or larboard line of failing. bearing, all the luips feering the fame courfe. In DLXIV. thefe cafes the fleet, by hauling the wind when in the ftarboard line, as in fig. I. will be ready to form the line on the ftarboard tack; and when ranged on the 2 larboard line of bearing, as in fig. 2. it will, by tacking, be ready to form the line on the larboard tack. N. B. 'Ihe arrows annexed to the diagrams on the plates, mak the direction of the wind, as in ordinary charts.

This firt order of failing is now feldom employed, exceot in pafling through a narrow ftrait. In the fecond order of failing, the fleet feering any proper courfe, is ranged in a line perpendicular to the direction of the wind, as in fig. a. 'this fecond order, befides being Fig. 3 . equaliy defecive with the former, is fubject to the additional difadrantage of rendering it extremely diffoult for the thips to tack, without each fhip falling on board that next a-ftern.

In the third order of failing, the whole fleet is clofe hauled, and ranged on the two lines of bearing, fo as to ferm an angle of 12 points, having the admiral's thip (A fig. 4.) in the nugular point, and the whole Heetrig. 4 : fteering the fame courfe. Thus, fuppefing, as in the plate, the wind at north, the ftarboard divifion of the heet will bear W. N. W. of the admiral, and the larboard E. N. E. This öder in finall fteets or fquadrons, is fuperior to either of the former,' but when the fleet is numerous, the line will be too much extended.

In the fourth order, the fleet is divided into fix or more columns, and is thus more concentrated. The commander!, ranged on the two lines of bearing, have their fquadions altern of them on two lines parallel to the direction of the wind ; the firt thips of each colunin being, with refpect to the commander of the fquadron, the one on his flarboard, and the other on his lartoard quarter. The diftance between the columns fhould be fuch that the fleet may readily be reduced to the thitd order of failing, and from that to the order of battle. This order is adapted for fieets or convoys croffing the occan, and is reptefented in fig. 5. But as it requires Fig. 5. much lime to reduce a fleel from this order to that of batule, it is defective when in prefence of an enemy.

In the ffth order, the lleet, clofe hauled, is arianged in three colunus parallel to each other; the van commonly forming the weather, and the rear the lee column. See fig. 6. Fig. 7. reprefents the f: me order, Fig. 6. and except that each column is herefubdivided into two, 7. with the bip bearing the commander of each fquadion in the centre of each fubdivifion.

In forming the order or line of battle, the mips of orter of the licet ase drawn up in a line nearly clofe han'ed, bathe.

Thin runs to leeward of fo many of the fleet as that each nip may readily fetch her wake, and then fleer a
courfe eight points from the wind, under an ealy fail. nip may readily fetch her wake, and then feer \({ }^{\text {a }}\)
courfe eight points from the wind, under an ealy fail. The line is formed by each flip in the fame manner as The line is formed by each int ip in the fame manner as
ii, the fill order, except that before bearing away, the line is perpendicular to the direction of the wind, or each flip has the wind on her beam.

As, in the third order of failing, the admiral's hip is in the centre; to produce this position, the fleet being in the centre; to produce this polition, the fleet being
formed in a line on one of the lines of bearing, and the flips fleering in each others wake, ten points from the Ships fteering in each others wake, ten points from the
wind, the leading or leewardmoft flip frt hauls her wind. The fecond flip does the fame as foo as the
gets into the wake of the former, and this is done by gets into the wake of the former, and this is done by each hip till the admirals thins haul their wind, when
they reach the wake of the leading hip. At the fame each hip till the admirals hips haul their wind, when
they reach the wake of the leading Chip. At the fame time that the admiral's ship hauls her wind, the fern-
mot half of the fleet does the fame. The thins are time that the admiral's ship hauls her wind, the ferm-1
mot half of the fleet does the fame. The thins are now in the third order of filing, from which the fleet can be formed in line of battle on either tack.
. To form the furtin order of failing (fee \(\mathrm{N}^{\circ}{ }_{58}{ }^{8}\) ), the failing.

To form a fleet in the first order of failing, fuppofing the Chips to be in no particular order, that hip which is to lead on the propofed line of bearing for the order of failing, runs to leeward of the greater part of the fleet, and then hauls her wind under an eafy fail. Each of the other flips then proceeds to take the proper fetation, by chafing the flip, which is to be a-head of her, and when in the wake of the leading flip, adjusts her quintidy of canvas fo as to preferve the proper diffance. The flips thus arranged attern of each other, are in the line of battle, and from this the firft order of failing is formed, by each flip bearing away at the fame time, and all fearing the propofed courfe.

In forming the fecond order of failing, the leading

As, in the third order of failing,
 free, 10 get ahead of the centre division.
2. Suppofe the weather and centre columns to interchange. To form the line under there circumflances; the centre flands on, while the weather column bears away eight

landing under cay fail, fo that each this may be at a
certain dillance from the flip immediately ahead, as a
cable's length, or half that difance. The firellips and
frigates a-heas and allen, form a line parallel to the
former, and to the windward of it, if the enemy be to
the leeward; but to the leeward if the enemy be to
svindward. 'this order is denoted by fig. 8. where the
fleet is failing on the starboard tack, with the wind at
north.
When a fleet is compiled to retreat before a superior
force, it is usually arranged in an order, the reverse of
the third order of waiting; the divisions of the fleet be-
ing ranged in the two lines of bearing, fo as to form an
angle of \(135^{\circ}\) or 12 points, the admirals ships being in
the angular point, and the frigates, transports, \&e. ir.
eluded willis the wings to leeward. See fig. 9, where
the sect is failing right before the wind. Though any
other direction may be taken, the two lines fill form
the fame angle.
The order of convoy is that in which the flips are
all in each others wake, flcering in the fame point of
the compass, and forming a right line. If the fleet is
numerous, it may be divided into three columns, which
azo to be ranged parallel to each other, that of the ad-
miracle occupying the center, and all leering the fame
course.
Having thus described the ordinary positions of a
fleet, we mut explain the manoeuvres by which they
are produced, and we shall begin with the orders of
commanding admins range themetelics on the iwo lyrics
of bearing, at a proper dillance from each other, Near-
ing the proposed course, and the this of the federal
columbus take each their if naive places ?
\(\begin{aligned} & \text { columns take each their respective places, parallel tofourh or- } \\ & \text { coach other, and forming lines in the diredion of the der. }\end{aligned}\)
Ta form the fifth order, the three leading hips of Fiftio order.
the divisions take their polls abieall and to leeward of
each other, keeping their wind under an cay lair; then
the Chips of each fquadton make fail, and take their
refpecive nations at the proper diflaze after of their
leaders, while the commanders of each division, and
the corresponding hips of each, keep mutually abrealh
of each other.
In forming from the firm order of failing, if the ships To form
are running large on the tack that anfuers to the line ihatine of
of bearing on which they fail, and if the line is to be battle.
 1

points, and having reached the wake of the centre, which now forms the van, hauls up; the fhips of the lee column tack together, and run under a grefs of fail, within two points free, fo as jult to gain the rear of the line; when they reta.k tagether (iee fig. 5.), or the lee column brings ta, while the centre fquadron bears away three points under eafy fail; and having reached the wake of the van, hauls up, to form the centre divifion.
3. Suppole the centre and lee columns to interchange. The lee column fands on clofe hauled under an eafy fail, the weather column beare aways two points under a prefs of fail, till it reach the head of the line, when it hauls up, and the centre bears away eight points, and when in the wake of the lee, now the contre, hauls its
Fig. 6. wind. (See fig. 6.).
4. If the weather and lee columns interchange; the lee column flands on under a prefs of fail clofe hauled, while the centre, under eafy fail, bears away two points, and when it reaches the wake of the now van fquadron, hauls its wind, and the weather column bears away eight points, hauling up when in the wake of the centre.
Fig. 7

Plate
DLXVI. (Siee fig. 7.).
5. Suppofe the centre column to form the van, and the weather the rear divifion. Here the lee column brings 10 , while the centre bears away two points, forming the line a-head of the former, now the centre, and the weather column vecrs away feven points on the other tack, forming the rear fquadron. (See fig. I. Plate DLXVI.).
6. To form the line fo that the lec column may form the van, and the centre the rear. The lee column is to ftand on under a prefs of lail, while the weather bears away three points under eafy fail, and the centre bears away eight points, the hips of each column hauling their wind, when in the wake of the now van divifion. (See fig. 2.).
7. If the line of battle is to be formed on the other tack, fo that the weather fhall form the van divifion, as in the firlt cafe, the fhips of the weather column firf tack fucceffively, while thofe of the centre and lee ftand on, the former tander eafy fail, and the latter fhortening fail, the leading fhips tacking when in the wake of the now van, taking great care that the hips of the centre and lee draw not too near to the fternmof
Fig. 3. Thips of the van, or to each other. (See fig. 3.).
8. To form the line on the other tack, when the centre and weather columns interchange. The weather calumn brings to, while the centre column flands on, till the leading thip be fully able to clear the weather cohumn, when the hlips of the centre tack fucceffively as they reach the wake of the van. The lee column ftands on, tacking fucceffively, as the fhips get into the Fig. 4. wake of the van, under moderate fail. (See fig. 4.).
9. In forming the line on the other tack, when the centre and lee interchange. The centre brings to, while the mips of the weather tack under hortened fail, and the lee under a prefs of fail ftands on, the leading nhip having gained the wake of the line, tacks, and is followed in fucceffion by her divifion. The centre column fills and ftands on, when the firt fhip of that column, and the latt of the lee, bear from each other in a direction perpendicular to that of the wind. (See fig. 5.).
10. 'T'o form on this fame tack, fo that the weather and lee may interchange. The weather and centre
bring to, while the lee crowds fail, till it can pals a-head of the weather column, when the fhips tack in fucceffion. As foon as the leading fhip of the centre, and the laft of the lee bear fiom each other in a line perpendicular to the wind, the centre fills, and tacks in fucceffion when in the wake of the now van, and the thips of the weather column do the fame when their leading finip and the latt of the centie are under fimilar circumftances. (Sce fig. 6.).
II. Suppofe the centre is to form the van, and the weather the rear, in forming the line on the other tack. The weather brings to, while the other columns make fail, till they can pafs a-head of the former on the other tack, when they tack fucceflively. The weather column, when the others have paffed it, fills, and tacks to form the rear. (See fig. 7.)

Naval Tactics
12. Suppofe now the lee column is to form the van. The weather and centre bring to, while the lee crowds fail, and tacks when it can pafs a-head of the weather column. When the laft hip of the now van has paffed to windward of the former weather column, the van fhortens fail, to give time for the other calumns to form, and the weather and centre fill at the fame time, to gain the wake of the van, when they tack in lucceffion. (See Fig. 8. fig. 8.).

We mult now thew how a fleet may be difpofed in To form the principal orders of failing from the line of battle; of failing and here, as before, we have feveral varieties. from the
1. To form the firf order of failing from the line of line of battle on the fame tack. All the fhips are to bearbattle. away together as many points as the admiral may direct, keeping in the line of bearing for the proper tack. The fternmoft firft bears away, and the others follow in quick fucceffion, to prevent running foul of each other.
2. If they are to form on the other tack; the leading fhip bears away four points to leeward, and the reft follow in fucceflion. The fternmon thip having bore away, the whole haul up, and will be in bearing for the line on the other tack. (See fig: 9 .).

Fig. 9~
3. To form the fecond order of failing from the line of battle, the whole fleet is to bear away together 10 points, fo that when the headmoft fhip, which firf preffes fail, fhall come abrealt of the fecond fhip, the fecond thip adapts her fail to keep in this bearing, and fo in fucceffion, each taking care to keep the preceding fhip in a line with herfelf, perpendicular to the direction of the wind. The whole fleet will now be before the wind. (See fig. Io.).

Fig. 10
4. To form the third order, the whole fleet is to bear away together ten points, the headmoft half, including the centre fhip, carrying a degree of fail to preferve their line of bearing, while each of the remaining thips is fucceffively to fhorten fail, fo as to form the other line of bearing with refpect to that on which they were before arranged. (See fig. I. Plate DLXVII.).

Plate
DLXVIr.
Fig. I. der on the fame tack. Of this evolution there are feveral varieties, but we ghall mention only two ; firf, when the van is to form the weather, and the rear the lee column, and the fleet to keep as much as poffible to windward. - In this cafe the van and centre tack together, and run clofe hauled in bow and quarter line, while the rear proceeds in its former courfe under eafy fail. When each hip of the centre is abrealt of the correfponding flip of the rear, the centre retacks,
while

Faval while the van fands on, till the centre and rear come actics. up, when it alfo retacks, and all the columns regulate their diflances. (See fig. 2.). Secondly, when the van Plate
LXVII, is to form the lce, and the rear the weather columnig. 2. The van bears away under eafy fail, and goes at right angles with the line a-head, while the centre runs two points free, each flip flecring for that flip of the van which is to be a breaft of her when in column. The diltance mult be determined by the leader of the van, who is not to haul up with her divifion, till the and the flernmoft fhip of the centre column are in a line at right angles with the wind, when both ftand on under ealy fail, while the rear crowds fail to pafs tu windward of both. (See fig. 3.).
6. To form the fifth order of failing from the line of battle on the other tack-of which there are alfo feveral varieties; but we fhall confine ourfelves to two: Firft, when the van is to form the weather, and the rear the lee column; the van tacks in fuccefion, while the leading thip of the centre is to tack when the leader of the van paffes him exactly to wind ward, in which the is followed by her divifion, and the rear mancuvres in the lame manner with refpect to the centre. (See fig. 4.). Secondly, when the rear is to form the weather and the van the lee column; the van tacks in fucceffion, and when about, either flortens fail, or brings to, to allow the other columns time to form. The centre and rear then crowd fail, and tack in fucceffion, the former tacking when its leader has the centre of the lee column in a line at right angles with the wind, or when its centre paffes a-tern of the lee column. When the centre has tacked, it regulates its rate of failing by the lee, and both wait for the rear to pafs to windward. The rear tacks when the leader has the firlt thip of the lee in a line at right angles with the wind, or when its centre 5. 5. Thip paffes a-ftern of the centre column. (See fig. 5.).

\section*{7. Fig. 6. reprefents the order of zetreat formued} from the line of battle, the whole fleet going four points free. This evolution is fo feldom required in a Britifh fleet, that we need not dwell on it.

There are various evolutions or manoeuvres performed by a fleet when in line of battle, fome of which we muft here defcribe.

Sometimes the fleet has to form the line on the other tack, by tacking in fuccefion. To do this, the leading fhip of the fleet tacks firft, after making more fail, or after the fecond has fhortened fail, to increafe the interval between them. When the firf thip is about, either the fecond makes more fail, or the third fhortens fail, and as foon as the fecond gets into the wake of the leader, the tacks, putting down the helm juft as the opens the weather quarter of the firf thip, already on the other tack. In the fame manner, each of the other thips tacks when in the wake of the leader; and the Thips already about mult preferve their proper diftances, by fhortening fail, if neceflary, till the whole fleet be on the other tack. If a ftip fhould mifs flays, fhe muft immediately fill again on the fame tack, and make fail with all poffible expedition, taking care not to fall to leeward. Thus fhe will get a-head, and to windward of the following flips, which will fucceffively perform their evolutions in the wake of the fhips that are already on the other tack, flanding on rather further than if the

But fuppofe the hips are not to tack in fucceffion.
To form the line on the other tack, the whole ficet veers toyether; the tear flip hauls her wind on the other tack, and flands on, while the reft go two points free on the other tack, and haul up as they fuccefively gain the wake of the leading thip. (Sce fig. 8.).

Fig. 8.
If the line is to veer in fucceflion, the van hip veers, and flands four points frec on the other tack, hauling her wind when clear of the fernmoft hip, and the reft follow and haul up in fucceflion. (Siee fig. 9.).

Sumelimes the flict has to turn to windward while in line of battle. The bell way to do this, when there is good fea-room, is for all the fhips to tack together, whes the flect will be in linc of battle on the one board, and in bow and quarter line on the other. If, however, the fleet be turning to windward in a narrow channel, it is beft for the flips to tack in fucceffion, as, were they all to tack together, the van would be foon in with the land on one fide, while the flern thip, foon after the fleet had retacked, would be too near the land on the other fide.

If the van and centre are to interchange; the van is to bear away a little, and then bring to, while the centre paffes on to windward, edging a little, to get a-head of the former van on the fame line; the rear, coming on under an eafy fail, edges away likewife, to gain the wake of the now centre fquadron. (See fig. 10.).

If the van and rear are to interchange; the van and centre are to bear away a little, and then bring to, fo that the van may bear away a little more to the leeward than the centre. The rear ftands on to gain the head of the line; and when a-breaft of the former van, the centre fills, and both flanding on, form a-head of the now rear, by edging down till they are in a line with it. (See fig. II.).

If the centre and rear are to interchange; the van ftands on under an eafy fail, while the centre bears away a little, and brings to, and the rear at the fame tinae carries a prefs of fail to pafs the centre to windward, and get into the wake of the van. The van ard centre then edge away to gain the line, with the now Fig. 12. rear 〔quadron, which then Ells. (See fig. 12.).

Several evolutions are required while a fleet is in the To nrancu. fifth order of failing, and of thefe we fhall notice fome rre in the of the more important.

When the columns are to tack in fucceffion, the fips of the lee mull tack firtt, as they have moft diftance to run, and when the leader of the centre comes a-brealt of the leader to leeward, or at right angles with the clofe-hauled line on the other tack on which the leader of the lee is now moving, fhe tacks and is followed fuccefively by the fhips of her divifion. The weather column mancuvres in the fame manner, paying the fame regard to the centre. Here the weather coiurn is fill to windward, and fhould the columns have clofed too much, or be too far afunder, the order may be recovered, either by the lee or windward column bearing away, fo as to make an angle equal to that propofed between any column, and a line joining the leader of that columa, and the fternmoft fhip of the next. (See fig. 13.).
When all the columns are to tack together; the Aternmoll hips put in Atays together; and when in flays, their feconds a-head put down their helms, and fo on through the whole fleet. Each colums will then be in bow and qquarter line. (See fig. 14.).

Naval
Tactics. \(\overbrace{\text { Plate }}\) DIXVII.

Fis. is fion fion, the hauls up. The fame evolution is performed by the centre and weather finps fucceffively, flanding on till they bring the point at which the lee column began to veer to bear in a right line to leeward of them. They likewife fucceffively fring their luffs when the point at which the lee column hauled its wind, bears right to leeward. (See fig. 15.).

Surpofe the fleet, when in the fifth order of failing is to tum to windward; let the hips be fo arranged that the leaders and correfponding fhips may be in the direction of the wind. The van Glips mult tack together, which are followed in fucceffion, each by the remaining hlips of the divifon, when they reach the wake of their leaders, or the fame point when they tacked; fo that there will always be three fhips in flays at once, till

When the weather and centre columns interchange; the weather and lee lie 10 , or only keep fteerage way. The centre column tacks together, and forming a bow and quarter line, goes clofe hauled to gain the wake of the weather column; it then tacks together, and flands on, while the weather column bears away to its new fiation in the centre, and the lee column fills. (See fig. Fig. 2. 2.).

When the weather and lee columns are to interchange; the centre column mut bring to ; while the lee flands on under a prefs of fail ; and when its fternmoll hip can pals to windward of the van of the centre column, that is, when the centre hip of the lee is in a perpendicular line to the direction of the wind with the van of the centre column, the lee column then tacks together, and fands on clofe hauled till it comes in a line with the centre column, when it goes large two points to get into the fituation which the weather column left; and then veers together, hauling the wind for the other tack. At the beginning of the evolution the weather column bears away logether under little fail, and goes large fix points on the cther tack, to get into the wake of the centre column; it then hauls to the form:r tack, going two points large, till it comes abrealt of the centre column, when it brings to, and Fig. 3. waits for the now weather column. (See fig. 3 ).

Suppofe the weather column is to pafs to leeward; the weather column is to fland on under eafy fail, while the centre and lee tack together, carrying a prefs of fail till they reach the wake of the weather column, when they retack, and crowd fail till they come up with it. The weather column, when the others have gained its wake, bears away two points, to gain its fation to leeward, when it brings to, till the other columns, now the weather and centre, come up. (Sce fig. 4.).

Suppofe the lee column is to pafs to windward. The weather and centre columns bring to, while the lee column carries fail and tacks in fucceffion as foon as the leading hiip can weather the headmont fhip of the wenther column; and when arrived on the line on which the weather column is formed, it retacks in fucceffion, forms on the fame line, and either brings to or flands on under eafy fail. If it brings to, the other two co-
lumns bear asay tigether two points, to put themreives a-brealt of the column row, to windward; Lut if the nuw weather column tlood on uncier an ealy fail, they may bear away only one point, to gain their proper dta(ions. (Sec fig. 5.).

It is of the greateft importance that each thip of a fieet or fquadron preferve her proper flation and diflance with refpeft to the relt. Thefe may be regulated in two ways, either by obfervation with the cưa. drant, or by what is called the naval fquare. This fquare is ufually confrucled in the following manner.

On fome convenient place in the middle of the quar confru ter-deck is defcribed the fquare \(A B C D\), fig. 6. having toman ant the fides AD and BC parallel to the keel of the thip. ufe of 1 Through the contre G, the line EF is drawn parallel to naval AD or BC , and the diagonals AC and BD are drawn. iquarc. The angles EGD, EGC are bifected by the otraight lines GH, GI, and thus the naval fquare is completed. Now the angles \(\mathrm{FGD}, \mathrm{FGC}\) are \(=4\) points each, being each half a right angle, therefore the angles EGD, EGC, the complements of thefe angles, are each \(=12\) points, and confequently the angles EGH, ECI are each \(=6\) points, being each half of the lan angles. Now, if a hip be running clofe hauled on the llarboard tack, in the direction FE, the direction of the wind will be IG, and her clofe hauled cuurfe on the other tack will be GC ; lut if the be running clole hauled on the larboard tack in the fame direction, her direction when clofe hauled on the flarboard tack will be GD.

Now, to apply the naval fquare to the keeping of fhips in their refpective ftations, fuppofe the fleet formed on the fifth order of failing, clofe hauled, the correfponding hiips of the columns coinciding with the direction of the wind, in order to run to windsard with greater facility. The correfponding hips in the column mult be kept in the direstion of GH, or GI, according to the direction of the wind and the tack they are on, while all the fhips of the fame column mult be in the diredion of EF. (See fig. 7.).

Again, fuppofe the hips arranged in three columns cn one of the lines of bearing, and clofe hauled on the other tack. The mips of each column will be in the direction of one of the diagonals, while the correfponding luips of the other columms will be in the direction of the other diagonal. (See fig. 8.).

Sometimes the line of battle is difordered on the To reftore wind's mifting, and requires to be reftored. Of this the order there are feveral cafes, a few of which we mall notice. batte, on
1. When the wind comes forward lefs than 6 points. wind. In this cafe the whole flcet except the leader brings to. The leading luip, that the fame diftances between the Ohips may be preferved on reitoring the line, feers a courfe as \(a b\) (fig. 9.), fo as to be at right angles with Fig. 9. the middle point between the former and prefent direction of the wind. His required courfe may be known by aoding half the number of points the wind has thifted to eight points, and applying this fum to the former clofe-liauled courfe. When the leader has arrived at the new clofehauled line with refpeet to the fecond fuip a.head, this nip immediately fills, ard bears away as many points as the leader; and when both thefe have reached the clofe-hauled line with refpeet to the third Ahip, fhe allo fills, and bcass away; and thus with the refl in fuccefion; and when they have got into the clofe-h,nulcd
aval clofe-hauled line \(b c\) with the fernmon fhip, they all Sits. haul their wiad together, and the fternmolt flip fills aind flands on clofe hauled.

This may te expeditiouny performed, if the whole fleet fall off as foon as the wind hifts, the fame number of points, and the leader bear away eght points from the middle between the former and prefent directions of the wind, or when the wind fh:ifs nearly fix points, if the leader bear away cight points from the piefent direction of the wind, and hauls her wind as foon as the flernmoif nhip bears from her in the clofe-hauled line, whle the lecond thip bears amay when the reaches the wake of the leader, and linuls her wind when the has aguin gained his wake. The third, furth, \&c. Mhips bear away, and alfo haul their wind in fuccefion, till the fternmoft and the whole line be furmed again. (See fig. 10.).
2. Suppofe the wind comes forward lefs than fix points, and the order of battle is to be reformed on the other tack. In this cafe all the mips are to veer round till their heads come to the requilite point with refpef to their former courfe, when the rear flhip, now become the van, hauls clole by the wind, followed fucceffively by the other fhips. Should the wind come ahead more than fix points, but lefs than twelve, the fleet is to manounvre as before, but if it flift exactly twelve points a-head, the tack nulk be changed.
3. Lanly, fuppofe the wind to mift oft-if lefs than two points, the leader hauls her wind, whils the fleet ftands on as before, each fucceffively hauling her wind as the gains the wake of her leader. If the tack is to be changed, the whole fleet tack together, and the fernmolt hip, now the leader, hauls up, white the reft bear down and haul up in fucceffion.
Should the wind change 16 points, all the fhips immediately brace about for the other tack, by which means the flcet will be going four points large; then the fhips inflantly tacking or veering together, the order of battle will be reftured or formed again on the fame tack as before the wind changed.

It is inconfintent with the nature of our plan to be more minute on the various evolutions of a fleet, when not in action with the enemy. Our nantical readers will find abundant information of this kind in the ufual works on maval tactics, efpecially the Elements and Practice of Rigging, Seamanffip, Naval Tąics, \&c. of which the lateft edition is in 4 vols 800 ; and The Syfem of Naval Taciics, with coloured figures, both publithed by Steel.

Having defcribed and illuttrated the principal erolutions which are performed by fleets or fquadrons under ordinary circumflances, we are prepared to confider the nature and confequences of a naval engagement.

In forming a fleet for battle, it is proper to confider the fize and number of the flips of which it is to confift, and the diftance at which they are to be placed with refpect to each other. In the prefent fytem of naval warfare, it is generally deemed of advantage to have the fhips that are to form the principal line as large as poffible; for though large fhips are not fo eaffly and exneditioufly worked as thofe of a fmaller fize, they are moll ferviceable during the action, both as carrytigg a greater weight of metal, and as being lefs expofed to material injury, either from the enemy's thot, or from
the weather. In boarding too, a large fthip muft liave greatly the fupsiority over a fmaller, buth from her gieater leeight, and from the number of hands which the contains. Wih relpect to the number of mips, it is of advantage that they be not too numerous, as if the line be too extentive, the fignals from the centre are with diniculty obferved.

In arranging a ileet in line of battle, it is proper to regulate the dulance fo that the fhips fhall be fufliciently near to fupport each other, but not fo clofe as that a difabled hip may not teadily be got out of the line without dillurbing the reft of the fleet.

It has loing been deemed a point of yreat confequence Advantages with the commander of a fleet to gain the weather gage, vand dilidror to get to windward of the enemy, before comirg to vanterages or action. In decidint on the propricty of this, much will gage. depend on the relative flreng:th of each fleet, and on the Itate of the weather at the lime. We thall fate the advantages and difadrantages of the weather gage, as they are commonly laid down by writers un naval tactics, though we may olferve by the way, that if a fleet be much fuperior to its opponent, it is feldom of confequence whether it cngages to windward or to lecward.

A fleet to windward of the enemy is thought to poffefs the following advantages. It may approach the Iteward fleet at pleafure, and can of courfe accelerate or delay the beginning of the engagement. If more numerous, it may fend down a detachment on the rear of the enemy, and thus throw him into confufion. It may alfo readily fend down fireflips on the enemy's fleet, when thrown into confufion or difabled. It may board at any time, and is fcarcely incommoded by the fmoke of the eneny. The reverife of thefe circumftances, of courfe, act againf a leeward fleet.

The difadvantages of being to windward of the enemy refpect chitly the cireumilances attending a retreat, thould this be neceffary. The windward fleet can feldom retire without paling through the enemy's line; and if in attempting to retreat, the windward fhips tack together, thofe of the leeward fleet may do the fame, rake the weather flips in flays, and follow them on the other tack, having now the advantage of the wind. in flormy weather, the windward flips can feldom open their lower deck ports, and the lee guns are not eatily managed after firing. Again, any dilabled thips cannot eafily quit the line without difordering the reft of the fleet, and expofing either that or themfelves to be raked by the enemy to leeward. A leeward flee: has the advantages of ferving their lower-deck guns in all weathers; of being able to retreat at pleafure; of drawing off without difficulty their difabled fhips; of forming with more readine's the order of retreat, or of continuing the action as long as convenient ; of having it in their porver when fuperior in number, to double the enemy, and of cannonading with great effect the windward hhips as they bear down for the attack.

As an engagement between two adverfe fhips is in fome meafure an epitome of an ergagement between two fleets, we thall firf briefly defcribe the former, as it takes place under ordinary circumflances, and thall then notice the ufual ranner of conducting a general engagement.

A naval engagement may be divided into three flages, the preparation, the action, and the repair.

Naval Tactics.

The action. When thefe neceflary preparations are completed,
and the officers and crew ready at their refpective fla-
When thefe neceflary preparations are completed,
and the officers and crew ready at their refpective flations, and when the two hips are fufficiently near each other, in a proper relative fituation for the fot to take full effect, the action commences with a vigorous can-
nonade from the great guns, accompanied by the whole full effect, the action commences with a vigorous can-
nonade from the great guns, accompanied by the whole efforts of the fwivels and fmall arms. The firing is feldom performed in vollies, as that would thake the thip dom performed in vollies, as that would Thake the thip
too much, but the guns are loaded and fired one after another, with as much difpatch and as little confufion
as pofible, care being taken to fire only when each gun another, with as much difpatch and as little confufion
as pofible, care being taken to fire only when each gun is properly directed to its object. During the firing, is properly directed to its object. During the firing,
the lieutenants traverfe the decks, to fee that the battle is profecuted with vivacity, and that the men do their duty, while the midihipmen fecond their injunctions, duty, while the midithipmen fecond their injunctions,
and give the neceflary affifance where required, at the guns committed to their charge. The youngcit of thefe gunscommitted to their charge. The youngelt of thefe
inferior officers are generally employed to carry orders from the captain. The gunners are all this time employed in the magazines, filling cartridges, which are carried along the decks in boxcs by the boys of the thip. When the action has continued fo long, or has advifable to bring her to an enogagent, orders are firt given to clear for aetion, which is begun by the boatfwain and his mates piping up the hammocks, in order to clear the fpace between decks, for the more eafy management of the guns, as well as to afford the men on the quarter-deck, \&c. a better protection againf the enemy's fhot, the hammocks being flowed in the nettings above the gunwale and bulwarks. After this, the boatfwain's mates go to work to fecure the yards, which is done by faftening them with ftrong chains or ropes in addition to thofe by which they are fufpended. They likewife get ready fuch materials as may be neceflary for repairing the rigging, if it flould be cut away, or otherwife damaged by the enemy's thot. In the mean time the earpenter and his mates prepare fhot plugs and mauls, to Atop any dangerous fhot holes that may be made in the bull near the furface of the water, and provide the neceflary iron work for refiting the chain-pumps, if their machinery fhould be injured during the engagement; while the gumner and his mates, and the quarter gumners, examine the guns, to fee that their charges are dry, and provide evely thing that may be required for fupplying the great guns and fimall arms with ammunition. The mafter and mafler's mates fee that the fails are properly trimmed, according to the fituation of the flip, and increafe or reduce them as may be found neceelary; and the lieutenants vifit the different decks, to fee that all is clear, and to take care that the inferior officers do their duty.
When the heftile fhips have approached within a proper diffance of each othcr, the drums beat to arms ; the boatfwain and his mates pipe all hands to quarters! All the men who are to manage the great guns repair immediately to their refpective fations. The crows, handfpikes, rammers, fponges, powder-horns, matches, and train tackles, are placed in order by the fide of the guns: the hatches are immediately clofed, to prevent fculkers from getting below; the marines are drawn up on the quarter-deck, \&c. the lanhings of the guns are caft loofe, and the tompions withdrawn. The whole artillery, above and below, is run out at the ports, and levelled to the point blank range, ready for fring.
produced fuch an effect, that one of the Thips mult yield or retreat, if the vanquifhed fhip cannot get oft, the acknowledges her inferiority by friking, or hauling down her colours, when the is, as foon as poftible, taken poffeflion of by the victor, the commander of which fends a part of his own crew into the captured fhip, and brings awey moft of her officers and men on board his own thip, as prifoners of war.

The engagement being concluded, they begin to re-Repair, \({ }^{99}\) pair; the guns are fecured by their breechings and tackles, with all convenient expedition. Whatever fails have been rendered unferviceable are unbent, and the wounded malts and yards Aruck upon deck, to be fillied or replaced by ohers. The flanding rigging is knotted, and the running rigging foliced where necellary. Proper fails are bent in the room of thofe which have been difplaced as ufelefs. The carpenter and his mates are employed in repairing the breaches made in the thip's hull, by thot plugs, pieces of plank, and theet lead. The gunner and his aflittants are bufied in replenifing the allotted number of charged cartridges, to fupply the place of thofe which have been expended, and in refitting whatever furniture of the guns may have been damaged by the action.

A general engagement between two adverfe fleets of Engag courfe involves a greater variety of circumflances, and ment be requires greater judgement, and more comprehenfive tween t skill in the commanding officer.

When the commander of a fleet has difcovered an enemy's fleet, his principal object, if he be fufficiently ftrong, is to bring it to action as foon as poffible. Every inferior confideration gives way to this important object, and all neceffary preparations are immediately made to prepare for fuch an event. The fate of the wind and fituation of the enemy will in general regulate his conduct with regard to the dipofition of his hlips on that oecafion. To facilitate the execution of the admiral's orders, the whole fleet is difpofed in three fquadrons, and each of thefe claffed into three divifions, under the command of different officers. Before the action begins, the adverfe flecis are drawn up in two lines, as formerly defcribed. As foon as the admiral difplays the fignal for the line of battle, the feveral divifions feparate from the columns in which they were difpofed in the ufaal order in failing, and every fhip crouds fail to get into its fation in the wake of the next a-head; and a proper diffance from each other is regularly oblerved from the van to the rear. The admiral, however, occafionally contracts or extends his line, fo as to regulate the length of his line by that of his adverfary. This is more particularly neceffary to prevent his being doubled, by which his van and rear would be thrown into diforder. When the holtile fleets approach each other, the courfes are commonly hauled opon the brails, and the top-gallant fails, and ftay fails furled. The movement of each thip is regulated chiefly by the main and fore-top fails and the jib: the mizen-top fail being referved to hatten or retard the courfe of the fhip; and by filling or backing, hoilting or lowering it, to determine her velocity. The fignal for a general engagement is ufually difplay. ed when the fleets are fufficienily near each other, to be within the range of point-blank thot, fo that the guns may be levelled with fome certainty of execution. After the battle has commenced, it is carried on much in the fame manner as between two flips, except that each
reliel of the ficet, befides atiending to ber own movements, has to oblerve the lignals made by the commanding officer, and repeated by the frigates on the van and rear. 'The chicf object of the adminal is to kecp his line as complete as poffible, hy ordering thips from thole in referve to fupply the place of tuch as may have been difabled, and to a:moy the cnemy as much as pullible, boik by frengthening the fecble parts of his own line, and, if circumblances admit of it, by fending down firellips upon that of the enemy. When the engagoment draters near a clofe, either by the deteat of the enemy, or by the difabled ftate of cither ileet, fignals are made from the admiral, to take poffeflion of fuch of the encmy's flips as have ftruck, to tow his own difabled hips into a place of fecurity, and either to clate the remainder of the enemy's Equadron, or, if that be impracticable, to draw off his own hips to be refited. *

Such are the general incidents attending an engagement at fea, modified of coule by numerous circumfances, of which a general defeription can convey no idea. There are, however, various movements and evolutions connected with a naval engagement, which it will be necefliary for us to notice.

Where the weather gage is deemed of fufficient importance, it is often an olject with two fleets to difpule it with each other. When the enemy is to windward, and it is wihed to gain the weather-gage of him, the theet to leeward fhould avoid extending itfelf the length of the enemy's line, in order to oblige them to edge down upon theirs, if they intend to attack them; which will be a mean, if they ftill perfill in doing fo, of lofing the advantage of the wind. It is impoffible for a fleet to leeward 10 gain to windward, fo long as the enemy keep the wind, unlcfs a change happens in their favour ; therefore all that a fleet to leeward can do mult be to wait with patience for fuch a clange, of which they will undoubtedly avail themfelres, as well as of any inadvertency the enemy may commit in the mean time. And as long as the fleet to leeward does not extend its line the length of the enemy's, it will be impoffible for the latter to bring them to action without ruming the hazard, by bearing down, of lofing the advantage of the wind, which both fieets will be fo delirous of preferving. That an admiral may takc advantage of fuch fhifts of wind as occafionally happen, he muft endeavour to get his fhips into fuch fituations where thefe fiifts mott fiequently take place. It is well known to experienced naval officers, that particular winds reign moft on certain coalls, or off certain headlands. Here, therefore, the admiral noould await the approach of the enemy; and though by this plan he may fometimes be unfuccefsful, he will more frequently gain a material advantage. The difpofition of projecting headlands, and the fetting of tides or curren:s, often contribute materially towards gaining the wind of the enemy. The flect to windward fhould keep that to leeward as much as poffitle abreaft of it; and thus, tnlefs the wind changes confderably, they will preferve the advantage they have gained. They fhonld alfo force them to keep their wind, unlefs they think it prudent not to engage, in which cafe it would be beiter to keep altogether out of fight.

When the enemy appears defirous of avoiding an action, there are various methods of attempting to force him toengage; as firft, whem he has the weather gage. In

Yol. XX. Part II.
this cale the lce flect, whiclı is defrous of Liraning on an engagement, mull keep always on the farne tatis with the enemy to windwad, taking care to l.eep i!. in o. 11 flipes fo cxaetly abreatt of the eneny, as to prevent lo. fing fight of them; and hence be ready to talie adra... tage of the firt favourable thift of wisd to make the attack. An alteration of the courle may be bett attempted in the night. The lee fleet munt have frigates on the look-out, and thefe muft contmally give novice by lignal of the mannouvres and courfe of the retheating Hect to windward. Thus the weather lleet is always expoled to purfilit, without being able to get off unfeen; bence nult fooner or later be compelled io an enigdseement, unlefs they can get into lume friendly poit, or thould be favoured by a grate of wind luftiment to diperle both fleets, and thus prevent the poflitality of a gencial engagement.

Secondly, when the enemy is to leeward. If the lee fleet keep clofe to the wind in the order of battle, we fleet to windward is to fand on in the fame manner till it be abrealt of the enemy, thip to hip, and at the fame time to bear away, and ffeer fo as to biing their refyective opponents on the fame point of the compafe with themfelves. Thus the adverfe fleets will be fufficiently near each other to begin the action, by each htip's prefenting hes bow to the hip abreat of her in the order of failing, which may be eatily changed for the order of batule, by all the fips hauling together clofe to the wind, in the moment which precedes the action. If the flect to loeward appear inclined to engage, it may brins to, to prevent lofing time, and after this they rill fill as foon as the action commences, becaufe it is ot advange to a lee line to be advancing alread. As the lee fleet fills and fands in clule by the wind, the meater line thould keep abreatt, before it bears away, 10 come within the requifite diftance, that the van ilip of the weather flect may always keep to \(n\) indwand of the leading thip of the lee line, and be guarded againtt any thitt of wind ahead.

If the lee fleet bear away four points to move their order of battle on the other tack, and avoid the action, filing off in fucceftion in the wake of the van lhip, the weather line, by bearing away all together eight pointc, cannot fail, as both fleets are fuppoled to fail equally, to pals through the middle of their line, and force thin to fight with difadvantage, if their extent be double the diftance between the two fisets. If the extent of the Heet be lefs than the above limitation, then the weather tleet will divide the lee fleet more unequally; and if the dillance between the fleets be confiderable, the weather fleet will be able to break through the line. If the lee fleet bear away four points all together, being of equal extent with the fleet to windward, ard their difance from each other equal to that of the length of one of the lines; thould the weather fleet bear away at the fame time eight points, they will approach very near the llernmoft of the retreating fleet; but they will not have it in their power to cut off any part of that tleet, even with an equality of failing; fo that the only advantage gained by this manouvre will be an ability of attacking the rear, and bringing it to action.

If the van thip and the reff of the weather fleet had a fufficient velocity to keep the centre flaip of the lee line on the fame point of bearing; in that cafe, the leading flip may break through the enemy's line about the
middle
midule thip of the centre divinon; for, fuppofing the tleets in the order of battle, on the flarboard tack, feering ealt, with the wind at fouth fouth-eaft, being at two leagues ditlance from each other, both the lines being four leagtes in extent; then the lee line bearing away all together four points, will run north-eaft ; while the nect to windward, bearing away all together eight proints, will fleer north; the van fhio of which will keep the centue divifion of the lee line in the point of beaning north-weft. As the is fuppofed to be able to continue in this pofition, it follows, that the van of the weather line muft clofe the centre of the flying line to leewad, afte: having run four leagues. The time and diknce neceffary to cut of a retreating fleet may always be known according to the laft fuppofition. If the lee Reet thould get on the other tack, and run large, ftill in the order of battle, they will be fooner forced to action by the weather tleet, who have only to bear away eight or nine points on the fame tack, or run right before the wind.

As in forcing a fleet to action, there are two principal cafes in which a flect may awoid an action, where circumflances are not fufficiently favourable ; firlt, when the enemy is to windward, and fecondly, when he is to leeward. In the former cafe the lee fleet fhould form the oider of retreat, if the enemy are in view, and run on the fame tack as their leading thip; but if he is mill out of fight, and they have received intelligence of his approach, by their frigates on the look-out, they may bear away large, without confining themfelves to keep the wind directly off, unlefs when in the order of retreat. In the fecond cafe, it feldom happens that the weather fleet can be forced to an engagement, becaule it can always ftand on that tack which increafes its diflance from the enemy; that is, by flanding on one tack while the enemy is on the other. The windward fleet mult of courfe not keep too near the enemy, and take all poffible means of avoiding being abreaft of tim.

It is often of adrantage to double the enemy; that is, to bring a part of the feet round upon his van or rear, fo as to place him betwcen two fires. This manœuvre alfo refolves itfelf into two principal cafes: firt, when the enemy is to windward; fecondly, when he is to leeward. In the firft cafe, the lee fleet that attempts to dauble the encmy, thould extend itfelf abreaft of him, fo that its van or rear may extend heyond his line, in order to overreach him, by tacking in fucceffion, fo that the extended part of the line may get up to windward. If this manceuvre be properly executed, it will be impoffihle for the thips of the weather line long to maintain their flations, for no veffel clofely attacked by two others of equal force can long refin.

It is of fome confequence to determine whether the attempt to double fhould be made on the van or the rear of the enemy, as on the propriety of adopting the one or the other of thefe meafures, may in a great meafure depend the iffue of the battle. In the prefent cafe, it is mof ealy to double the van of the enemy, becaufe if they are engaged by the thips abrealt of them, thofe which are advanced ahead will be able, by making all fail, to get in the perpendicular to the direction of the wind with the van of the enemy, and tack in fucceffion \(t 0\) gain the wind of them on the other board, thus keeping thern to lecward; and when they are come fuflicient.
ly to windward, they are again go about, in order to I Navat keep the two headmoft thips of the enemy's line coninually under their fire. If there be two or three thip.s to tack in fucceffion and gain the wind of the enemy, t'iey may edge down on the van of the water line at pleafore, kieping themfelves a little to windwatd of it; and as that van is already engaged by the other thips ab:catt on the othe fide, the mul neceffarily be foon difabled. If they bear away, they mult drop upon the line with which they are engaged to leeward, while the Ghips to windwa:d ftill continue to cannonade them. If they attempt gring about, in order to attack more clofely the hips to windward, they will be raked, while in Itays, by their opponents to leeward and to windward, who enfilading them with whole broadfides, which they cannot return, muft complete their diforder. If they make fail, in order to fruftrate the defign of the mips inclined to double, thofe with which they are engaged abreaft to leeward have only to perform the fame ma. noeuvre, and keep them under their fire; while the others, after having haraficd them as much as poffible, will do their beft to perform the fame mancuvre on the fucceeding thips.

If any of the thips in the van of the weather line are difabled in their mafts or yards, they will drop attern, and run fcul of the next fucceeding flup, and thele again on the next allern. Thus, the enemy's order of tattle will be broken, while on the other hand the lee line is preferved; and thofe thips which have gained the wind of the enemy will, without engaging more fhips than they can manage, contribute to increale the confufion.

When the enemy is to lecward, and the weather flect attempts to double, the thips of the weather line muft extend their van beyond that of the enemy, and then veer in order to bring the headmoft hips of the lee line between two fires. It muft not, however, be concealed, that it is much more dangerous to the fhips engaged in this fervice to attempt doubling a flect to leeward, than one to vindward, as if difabled, or feparated too far from their own fleet, they cannot fo eafily extricate themfelves, and rejoin the fleet.

When one fleet attempts to double another, this latter will of courfe do all in their power to avoid the im pending danger; and this they will the more readily do, according to their number, or their fituation. If the Heet thus threatened be to windrard, one of the methods propofed to avoid being doubled, is to extend the line towards the point threatened, fo as to leave a greater fpace between the fhips; but in doing this, there is a rifk of having the line broken by the fuperior enemy. Another method fuggefted is, for the flag hips of the windward fleet to oppofe themfelves to thofe of the lee line, which is fuppofed to render feveral of the enemy's Aups in the intervals of little ufe; but one great inconvenience of this manceuvre is, that it leaves the vam and rear mof expofed to the enemy's fire, and that the rear divifion in particular is in great danger of being doubled. To remedy thefe defects, the largeft flups hiould be placed in the van and rear of each divifion, and the flect muft regulate its failing in fuch a manner that its rear thall never be aftern of the rear of the enemy.

When the enemy is to leeward, the weather lleet is to keep aftern of the enemy, fo that the van of the weather tleet, may bevoppofed to, and attack the eneny's contre. Hence the encmy's van will bccome ufelefs for fome

Naval fome time; and fhould it atternpt to tack and double on the weather fleet, much time will be loft in performing that cvolution; and it alfo runs the rilk of being feparated by the caln which often happens in the courle of an engagement, occafioned by the difcharge of the guns. - A confiderable interval might allo be left between the centre and van, if necelfary precautions be taken to prevent the van from being cut off.

There are feveral circumitances of importance to he confidered in the fubject of chafing, i. e. when one hiip or fleet purfues another, called the chafe, either to bring her or them to action, or to oblige them to furrender.

When a fingle fhip chafes another, it is to be prefured in general, that one of them is the better failer, though this is not always the cafe, and Atill by proper manœuvering the chafing flip, or cbafer, may gain on the chafe. In the following obfervations, however, we flaal! fuppofe the chafer to fail fatter than the chafe. The manceuvres of the chafer will depend on her being to windward or leeward of the chafe.

When the chafe is to windward, it is evident that as foon as the perceives a ftrange thip which the takes for an enemy, the will haul her wind, in order to prolong the chafe, as otherwife her retreat would foon be cut off. The chafer then ftands on alfo nearly clofe hauled, till the has the chafe on her beam; the then tacks, and fands on clole bauled till the chafe is again on her beam, and then retacks. In this mamer fhe continues tacking every time fhe brings the chafe perpendicular to her courfe on either board; and by thus manœuvring, it is certain that the chafer will, by the fuperiority only of her failing, join the other in the fhorteft time. For fince the chafer tacks always as foon as the chafe is perpendicular to her courfe, the is then at the fhorteft diftance poffible on that board; and fince the chafer is fuppofed to be the fater failer, thefe thorteft diftances will decreafe every time the chafer tacks. It is therefore of advantage to the chafe to keep conftantly on the fame courfe, without lofing her time in going about, as tacking cannot be fo favourable to her as to her adverfary, whofe failing is fuperior. If the captain of the chafer thould to little underfand his profexion as to fland on a long way, and tack in the wake of the chafe, the beft thing the can do is to heave in ftays, and pafs to windward of him on the other tack, except fhe fhould find herfelf likely gaining advantage by going large; for if the chafer perfifts in tacking in the wake of the other flip, the purfuit will be very much prolonged.

When the chafe is to leeward, the chafer is to fleer that courfe by which the thinks the will gain moft on the chafe. If, after having run a flort time, the chafe is found to draw more aft, the chafer flould then bear away a little more; but if the chafe draw ahead, the chafer fhould haul up a little, and thus the courfe may be fo regulated that the chafe may always bear on the fame point, and then the chafer will get up with the chafe in the thorteft time poffible; for if any other comife were fteered, the chafer would be either too far ahead or too far aftern, and hence the purfuit would be prolonged. The chafe fhould run on that courfe which will cariy her directly from the chafer, and fhould confider which is her heft trim with refpect to the wind, that the may move with the greateft poffible rapidity from the chafer; for fome fhips bave more advantage in
going large, others with the wind right aft, and others when clole hauled.
Another method has been propofed for chafing a hipip 86 to leeward, that is, by conftantly fleering directly for Gurve of the chafe: in this cale, the tract defribed oy the chater purfure. is called the line or curve of purfuit. 'Io illuthate this, let A (fig. 1 i. Plate DLXVMI.) repreient the chaler, Pate and \(B\) the chafe directly to leeward of her, and runaing Fig. 11 . with lels's velucity than the purfucr, in the direction BC, perpendicular to that of the wind. Now, to conftruct this curve, Ict \(\mathrm{B} b\) be the diflance run by the chafe in any fhort interval of time ; join \(A 6\) and make \(A x\) equal the dillance run by the chater in the fane time. ^gain, make \(b c, c d, d e, e f f\), \&cc. each cqual to B6; join \(1 c\), and make \(1,2=A 1\); join \(2 d\), and make 2,3 equal to A1; proceed in like manner thll the two dillances carried forward meet as at C , and a curve deferibed through the points \(A, 1,2,3, \&<c\). will reprefent nearly the curve of purluit; and the lefs the interval A I is taken, the more accurately will the curve be formed. In this particular cafe, the length of the diflance \(B C\) may be found as follows, provided the diflance \(A B\) and the proportional velocities of the two nilips be known.

Let the velocity of the chafe be denoted by a fraction, that of the chafer being unity. Multiply the given diffance \(A B\) by this fraction, and divide the product by the compiement of the fquare of the lame fraction, and the quotient will be the diftance sun by the chafe B. Suppofe AB, the diffance of the chafe directly to leeward of the chafer, be taken at 12 miles, and fuppofe the relocity of the chafe three-fourths of that of the chafer; what will be the diftance run by the chafe before fle is overtaken? Now \(\frac{12 \times \frac{3}{4}}{1-\frac{5}{4}}=\frac{9}{18}=\) \(9 \times \frac{16}{7}=20 \frac{4}{7}\) miles; and fince the velocity of the chafer to that of the chafe is as 4 to 3 , hence the diftance run by the chafer will be \(=20 \frac{2}{7} \times \frac{3}{4}=27 \frac{3}{7}\) miles. As the chafer alters her courfe at every point, and probably fails better with the wind in one direction with refpect to her courfe than when the wind is in anotlier direction, her velocity will be different at different points of the courfe. Thus, fuppofe her to fail falter when the wind is on the quarter, her velocity will conftantly increafe to a certain point, and will then diminith. Hence in real practice the curve of purfuit will not be exactly what is laid down in the above problem, and of courfe the meafure of \(B C\) will differ a little from what we have there laid down. See Resistance of Fluids and Se:manship.
If the whole fleet is to give chafe, the admiral will In the caie make the proper fignal, and then each fhip will inftant- oi flects. ly make all the fail poffible. If the retreating fleet is not much inferior to the other, a few of the fafteft failing vefiels only are to be detached from the fuperior ficet, in order to pick up any ftragglers, or thofe fhips which may have fallen aftern; and the remaining part of the fleet will keep in the fame line or order of failing as the retreating fleet, fo that they may, if peffible, force them to action. But if the retreating fleet is much inferior, the admiral of the fuperior fleet will make the
fignal

Naval fignal far a general chafe, and then each mip will im. '1actics. nediatcly crowd all the lail ponlible after the retreating Acet; or, if the chafe be ftill lef, numerous, the admiral will detach one of the fquadrons of his tleet, by hointing the proper fignal for that purpote, and he will follow with the semainder of the fleet. The lquadron that chafes, fhould be very careful not to engage too far in the chafe, for fear of being overpowered; but at the fame time to endeavour to latiofy themfelves with regard to the object of their chafe. They muft pay great sittention to the adniral's fignals at all times; and, in order to pecvent feparation, they mould collect themfelves before night, efpecially it there be any appearance of foggs. weather coming on, and endeavour to juin the fleet again. The hlips are diligently to oblerve when the admiral makes the fignal to give over chafe ; that each regarding the admiral's hip as a fixed point, is to work back into her ftatio", to form the order or line again as quickly as the nature of the chafe and the diAance will permit.

When a flect is abliged to run from an enemy who is in figit, it is ufual to diaw up the hips in that form or order, ealied the ordor of retreat; and the admiral, when hard purfued, without any probability of efcaping, ought, if practicable, to run his thips athore, rather than fuffer then to be taken afoat, and thescby give additional ftrength to the enemy. In fhort, nothing fhould be nezleeted that may contribuie to the prefervątom of his fleet, or prevent any part of it from falling inis the hands of the conqueror.

We have now one though the principal cvolutions of Alects and fquadiuns, nearly as they are defcribed in the Elcments of rigging. Seamanhip, ant naval tactics, and other approved publications on fimilar fubjects. We have indeed umitted the me:hod of forcing an enemy's line, and of avoidiug beirg forced, becaule the formor will be readily underfood from what we have to add on the improved method of tactics of MI. Grenier, and MIr Clerk of Eidin.
\(D=f\) ecis of the mual
line of batte. Various defects have been obferved in the tactics ufually employed at fea, efpecially in a line of baite, and is the mode of bringing an enemy to action. The ufual or P of battle firt introduced by the duke of Fork, atie wards James 11. of England, is defective from its le ealit. Its great extent makes it difficult for the admiral windge what orders are proper to be iflued, to the thips fationed at the extremities, while his fignais, however diltincty made, are liable to be miltaken hy the commanders of thefe fhips. Befides, the extrem ties of a lang line, efoecially if it be to leeward, are nectfar ly defencelefs, as the enemy may throw himilelf with a funerior force on the van or rear, and cut either of thefe of before it can be properly fupported by the other fyudrons. Vifcount de Grenier, who was, we believe, one of the firlt to notice thele defects, propo. ful to remedy them by introducing a new order of

\section*{89}

of de Girenies's methind of tac ties.

Prlate
DLXVill
Fige 12. battle.

The leading principles of De Gremier's tactics are founded on the following confiderations. It is evident that each hip of a tleet mutt at all times occuny the centre of a ectain horizon. This hgrizon D: Grenier divitos inio two unequal parts, calling the greater the dirch and graduatet frace, and the lefs the indircet, crofed, and ungraduated fpacc. 'The realon of thefe ap- pellations is, that on the greater legment of the horizon-
tal circle there are 20 difierent points, which may be masked by degrecs from one of the clofc-hauled ines to the other, and to which a foip may fall from the centre by fo many direct courfes without tacking; whereas from the other 12 points, including that from which the wind blows, here cannot arrive but by iteerng crols contes, which muf necefarily delay her progrels. Suppufe now a flee: to leeward, to citpoted that only a part of it can fight with another equally numerous, and ranged to windward in a fingle line, and let the lee fleet be ranged on three fides of a lozenge \(a b, c d, c f\), (fg. 12.). The fquadron \(a b\), which is matt to whidward, being drawn up in line of battie, camnot be fought but by an equal number \(\mathrm{AB}, \mathrm{CD}, \mathrm{EF}\). All the reft of that fleet therefore mutt remain inaclive, wnlefs the hlips which are not engaged fhould thy to pals to lecward of the fleet a \(b, c d\), ef. Hut fhould the fhips of the weather flect, which ate placed between I; and \(F\), bear away as they appear in the figure betwces \(\mathrm{C} i\) and \(\mathrm{F} i\), the fips between. \(A\) and \(\mathcal{E}\), which are fighting to windword, cannot bcar away with them. Suppole now that the thips between \(C i\) and \(F i\) have pafled to leeward, the fquadrons \(c d\), ef, which ate ranged accorking to De Gienier's fyftem, and have not yet been engaged, hould come to windward and join with their friends \(a b\) agninh that fquadron of the enemy AB which is dill to windward and engaged; it is almof impofible but that the fjuadron AB mut le defiroyed by fo great a fuperiority, before it could receive affitance from the mips to leeward between \(C i\) and Fi.

De Grenier propofes only three orders of failing, one His orlers when a fleet is 10 pafs a frait; a fecond when it fleersot fulting. in open fea, on the look out for an enemy, or with a view to avoid him; and a third when on an extenfire cruife difpofed fo that it cannot be eafily furprifed or broken. Of thefe three orders only the fecond and third differ from the ufial orders of failing. The former of thefe is reprefented by fig. 1. Plate DIXIX. where the columns \(a b, c d\), ef, are difpofed on three fides of a regular lozenge, on the two clof-hauled lines. The Yig. I. atai nhips of the two divifions \(c d, c f\), fometimes to windward (as in fig. 2.) and fometimes to leeward (as in fig. 1.) of the third divifion \(a b\), are to be formed on two parallels of one of the clufe-bauled lines in the wakes of their refpective headmut thips; while the third divition \(a b\) is to be ranged ahead or aftern of the others on the other clof-hauled line, feering chequerwife the fame courfe as the other divifions.

When \(a b\) is to windward of \(c d\) and \(e f\) (fig. 1.), \(\mathrm{D}=\) Grenier calls that the quindward primilue order of failing, and when to leeward (Gig. 2.), the Heet is faid to be in the lecward prinitive order of failing. 'Thefe are the two principal poftions in almolt cvery cafe, and with very little variety, may become the order of battle, of chafing, \&c.

His third order is illuffrated by fig. 3. where the di. Fig 3 . vifions \(a b\) and \(c f\), are fuppofed at the dilance of about fix leagues from cach other ; \(c d\) and of refting on the extremitics of the bafe of a triangle SJV, while the centre flip of the divifion \(a b\) refts on its fumenit 7 ; none of the divifions could be cut off by an enemy, huwever formidable, feen from its centre flip at the diftance of fix leagucs. For if, on the proper fignal, the divifron a \(b\) notuld necr from \(T\) toward \(X\), on the courle oppolite
oppofite to the ctore-iauled line it ficered before, and the fiwo divifiens \(r d\) and \(e f\) flec: from \(V\) and \(S\) towards X itkewife, it is plain that eacin of thefe divifions would have only 1 h ase leagues to sun to join the other two, while the enerny winich was fint penceived at the diftance of fix leargues, muft rum nine beforc he can come up with the nearelt of thete fquadrons.

To form De Gecnier's order of balle reprefented in fig. 4. and 5 . it will be fueficient for the flitips of the three divificus ranged in the winduard primitive order of lating (fee \(\mathrm{N}^{\bullet} 90\).) to heave in flays all) together, and get on the other racks on the oppiolite line of bearing (fig. 4.) ; or for the thips in the leeward primitive crder at once to haul the wind on the fame tack as they iteor; and they will find ihemielves in order of batte, fyrg 5 . When the two cclumes \(c d\) and \(c f\), are to lectiand of the third division ab, ranged in order of battle, this is called the natural order of boulte, and when \(c d\) and of are to windward of \(a b\), this is the inverted creler of baithe. The former of thefe is ralculated for a licet combating to leeward, and the latter for a flect which mult fight to windwarel.
To explaia the advamtages of the difpoftions, let us fuppofe the line \(A B, C D, E F\), fig. 6 . to reprefent an enemy's fleet to windward in the ufual order of battle, on the clofe-hanled line, and on the flartoard tack, and let \(a b\) be one of the divifions of a fleet dilpufd according to the now natural order, on the flarboard tack, while the line \(c d\), ef , reprefent the other two divifions ftanding on chequervile on the fame tack, but fnrmed on the oppofite clofe hauled line. When the enemy comes to attack this latter flect on a fuppontion that it is inferior to their own, their divifoas AB and EF , in order to attack the hiips \(a\) cr \(b\), mult bear away. Now, to preverit the altack, each of the divifions \(c d, e f\), muft make the following evolutions according to their refpective fituations, and the manceuvres of the enemy. 1. The flips of the divifion \(a b\) arc to flacken as much as polfible their lieadway, and form a very clofe line, till the enemy makes a movement to attack the headmott or fernmof thip of that divifon. 2. The hips of the divilioa \(c d\) are to make fail till they corne under the fecond or third fhip of the rear of the line of battle \(a b\), when they will take the fame fail as the hips of that divifion, to preferve that pofition until the hoffile flips make their evolution to attack the rear fhips of that divifion. In this fituation the thips of the divifion \(c d\) will be able to obferve the manoeuvres of the enemy, in order to change tack, and form themfelves in order of batile on the oppofite board as foon as the hoffile fhips Thall have run over a certain fpace; becaufe the fhips of the divifion \(c \boldsymbol{d}\). fteering afterwards clofe hanted in the wake of the fternmoft thip of the divifion \(a b\), will be able to cover the rear fhips of that divifinn, and get the weather-gage of the honile divifions which are bearing away; ralic their thips; run along fide of then ; double their rear-guard, and put it between two fires, if thofe luofile fhips are following is the wake of each other di. vide it, if they bear away chequerwife, or gain to windward, and put between two fires the enemy's divifion \(C D\), while engaged with the divifion ab. 3. The divifion of may abandon their pof, and run chequenwife under a-prefs of fail as foon as the enemy falls alead of \(a b\); that if the eneny's's divifion AB attempts to fa!t on eff, or on the van of \(a b\), they may, by going about,
flece in order of batlle clofe hauled on the oppofice line, and cover the (hip) a, double the honile divifion (1) ahead, or divide \(A B\) which is runnmg chequervite on the oppolite tack.
lig. 7. marks another method of marocurring by the Fij. 7. divifions \(d\), \(f f\), when the ene my's flips are arrainged in a fingle line not well formed.

Figs. 8. and 9. illuffrate De Grenier's method of De Gireplacing the admiral's mip, and the frigates and tranforter's nuepoits aittached to a lleet. A, fig. 8, is the admirat that of arplaced ahead of the fleet, at a llort diltance from the ranging the heacmoff of the fecond divifion, and in the fame dirce- flup, frition of the wind as the headmost mip of the firt divifion; gates and If are two figates obferwing the lame rule and pofition tranjports. With refpect to the van flip of the third, and rear of the Figs. 8 a and firl divuion. When the flect is in order of battle, as in \({ }^{90}\) fig. g. the admiral's fhip \(A\) is in the centre of the lozenice, and twa of the frigates. \(f f\), on the fourth fide of lozenge. The tranfports and fore-flips, when the flect is in order of filling or conroy, occupy the fpace cir. cumfrribed by the lezenge, but in order of catile they a:e difored in a line oppufite to that of the encmy.

We cannot enter on a more minute or Catislactory ac. count of this fytlem; for a lull expofition of which we mult refer to the original work entitled \(L^{\prime}\) 'Art de Cuerre en Mer, ou Thatique Navale, \&zc. par M. le Vilcompte de Grenier, or the extracts from it contained in the Elements and Practice of Rigging and Seamanjbip.

TVe mult now turn our attention to the improvements.inc cilerk'z in tactics fuggened by our countryman Mr Clerk; - \({ }^{\text {tactics. }}\) improvements which have received the approbation of [everal diitinguilhed officers of the Britith navy, and to hints derived from which we are in a great meafure indebted for fome of the mort fignal victories which have heaped additional honour on the naval power of Britain.

Before entering on an explanation of Mr Clerk's tac- Mr Citerk's tics, we must briefly flate his objections to the ufual to the ctious method of bringing thips to action, by the weather fhip to the urot of or Alcet fleering directly down upon the enemy. Bywuack. doing this, the enemy to leervard often has an opportunity of completely difabling the Guips making the attack, as the furmer can ufe ali their guns on one fide, while the latter ean only ufe their buw chales. Suppofe B, fig. io. Plate DLXIX. to reprefent a hip of So guns to windward, in fight of an enemy's finip of Dixix equal force F , to leeward. Now, if B bears down di-Tig. to. rectly upon \(F\), the latter, by lying to, as in fig. II. and 11 . will prefent a broadfide of 42 guns, all bearing for a confiderable time on B, whic the latter coming down headwife, can only bring the two light guns of lier forecafle to bear on \(F\), not to mention that \(F\), by lying brnadfide to, will have her mafts and rizging litte expofed to the encmy's fhot, while B flarding head on, is expoled to be raked by every thot from \(F\), and in particular her rigging is in the utmoll donger.
Inflead of this objeationable made of attack, Mr His mi or Clerk propofes that 13 having the vind, fhould run ...toot. down altern as in the dotted line at fir. I2. till fhe gets Fizs \(x\) zo into the courfe of \(E\), near her wake, or in fuch a pufi- and 13. tion as will bring her parallel to F 's courre, and within a proper ditance, when the can run up clofe along fide of \(F\), and engage on cqual terms; or, that fle ilsonld floot ahead, then veer, and wun down on the weather bow of \(F\), as in fig. 13 , till fla can forco the chafe to

Frincipies on which the bringing of nips to action is founded. Figo.I7.
bear away to leeward, kceping clofe by her, on equal terms, taking care in both cafes not to put it in the power of F to bring her broadfide to bear on her without retaliation.

Fig. 14. is employed by Mr Clerk to illuftrate the different procedure of a French and Britifh man of war in fing, the former at the rigging, and the latter at the hull of the enemy, with their effects. Let \(F\) reprefent a large hip defirous of avoiding a clofe engagement, but lying to, to receive with advantage an enemy's hip B. of equal force. Suppofe that \(F\), by firing at the rigging of B , may have carried away fome of the principal ftays, feveral of the windward florouds, a fore-topmalt, or other rigging of lefs confequence, without having wounded a fingle man; and fuppofe a fecond fhip confort to F , receiving an enemy's thip like B , but fring only at her hull, fo as to kill 30 or 40 men, without damaging her rigging. Now, when \(F\) and her confort wifh to avoid a clofe er.gagement, it is evident that that hip \(B\), which has lof part of her rigging, is much more difabled from coming to elofe action than her confort whofe rigging is entire, though the may have loft a great number of her men.

By the feheme at fig. \(15 . \mathrm{it}\) is intended to illuftrate the imponfibility of one fhip being expofed to the fire of many fhips at one time. Let I, H, F, H, I, reprefent five thips in line of battle ahead, about a cable's length, or 240 yards afunder, and fuppofe the length of each nhip to be 40 yards, fo that the whole fpace between the head of one flip and the head of that next adjacent equals 280 yards. Let the perpendicular line FK , extending from the beam of \(F\) fix cables lengths or \(144^{\circ}\) yards, be divided into fix equal parts. It is evident that any Mip flationed at E in the line \(\mathrm{IK}, 720\) yards diftant, cannat long be expofed to the fire of more than the centre flip \(F\) of this fquadron. For if we luppofe that H and K ahead and allern of F , can bring their broadfides to bear on E ; by putting themfelves in pofitions for that purpofe, they will not only diforder their nwn line, but one will leave her head and the other her fern expofed to a raking fire from the oppofite hips BB in the enemy's line. If B can fuffer little from the two hips \(\mathrm{H}, \mathrm{H}\), at the diftance of 720 yards, it is evident that the will fuffer ftill lefs from thefe fhips as the approaches nearer the enemy's line. Again, if inflead of a eable's length afunder, we fuppofe the chips I, F, I, two cables length afunder, to bear on the fhip B. It is evident from the figure that in this cafe \(B\) will not be more expofed to the fire of I and I at the diftance of I 440 yards than the was to that of H and H at half that diflance; and fo in fimilar cafos.

In explaining the principles on which we are to judge of the advantages or defects of different modes of bringing thips to action, Mr Clerk fuppofes a fleet of 10,20 or more thips of 8 כ guns each, drawn up in line of battle to leeward, as at F, fig. 16. and lying to with an intention to avoid an action; while another flect, as B, of equal number and force, alfo drawn up in line of battle, three or four miles to windward, withes to make an attack, and come to clofc quarters on equal terms. The fleets being thus difpoled, thould the Heet at \(B\) attempt running down to attack the flect at F, cach hip flanding liead on to the oppofite thip in the leeward line, it is to be expected, from what we lave already \#ated, that the attacking flips will be difabled, at lealt
in their rigging, before they can come to clofe action; but fuppofe that the commander of the weather fleet, though his hips have been dilabled in their, rigging during their courfe a a a to leeward, fig. 17. has made them bring to at a great ditance, but fufficiently near to injure F . This latter Heet, whiclı has been endeavouring to avoid an acion, will now bear away with little injury to a new flation, as \(G\), and there remain out of the reach of B 's hot, and this fleet muft repair its rigging before it can make another attack.

Again, fuppofe that the fleet B, inilead of flanding Fig. 18 . head on, were to run down in an angular courte, as at fig. I8. It is plain that if any hiip in this angular hine noould be erippled, her defect in failing will occafion a confufion of leveral of the oiher thips in that line. It may be faid that the floppage of one fhip a-head will not neceffarily produce a ftoppage of every fhip a-ftern of her, becaufe they may run to leeward of the difabled thip; but we muft obferve that by this time the dips a-head in the van \(A\) may be engaged, and confequently not having much head way, are nearly flationary, lo that each hip a-flern, in attempting to bear down as at \(\mathrm{D}, \mathrm{D}\), muft be confined to a certain courfe, and muft run the rifk of being raked in coming down before the wind, and confequently of being difabled before coming up with the enemy.

Thirdly, the van of the ficet \(B\) having attained their Fiz. 19. fation at \(A\), a-breaft of the van of \(F\), fig. 19. and having begun the action, the van hips of \(F\), with a view to retreat, may throw in a broadfide on the van of \(B\), and then bear away in fuccellion, as at H , followed by the reft of the flet F , which, after exchanging broadfides with the van of B, may draw up in a new line two or three miles to leeward at II, fig. 20.

Suppofe again, for further illufration, that B, fig. 1. Plate DLXX. reprefents a fleet putting before the wind, each ihip intending, when brought to at a determined diftance at \(A\), to take up her particular antagonills in the line of the enemy F to leeward; and let F be fuppofed at reft, without any motion a-head. It is eafy to conceive that while the alternate fhips of F's line, under cover of the fmoke, withdraw from battle to GGG, the intermediate hiips left behind them in the line will be fufficient to amufe even the whole of B's fleet, till the fhips \(G\) thall form a new line HH as a fupport from the leeward. In fuch cafe B, after being difabled, and not having forefeen the mancuvre, will neither be able to provent the intermediate fhips with which he is engaged from bearing away to join their friends, nor, were he able, would it he advifable to follow them, for the fame mancuvre with equal fuccefs can again and again be repeated.

To explain the relative motion of thefe two fleets, let Fig. \(\approx\) F, fig. 2. ren refent a fleet of 12 hlips in line of battle, a cable's length a funder, and fuppofe the length of each thip from the end of the jib-boom to the ftern to be \(36 \frac{2}{3}\) fathons. The whole fleet will occupy a fpace of two Englifh miles; and if it be fuppufed to fail in the direction FG , at the rate of four knots an hour, it will in an hour have noved to \(G\), four miles from its former pofition.

Now, let there be an oppofite fleet B, alfo 12 hips, fituated four miles to windward, and let the point A be a quatter of a mile right to windward of the point \(G\). Then, if \(B\) by bearing away in the dinection BA, gain
the point \(A\) at the fame time that the lecward feet \(F\) has arrived at \(G, B\) will have moved nearly at the rate of \(5 \frac{1}{2}\) miles an hour, and the angle contained between the direction of its line of bearing and its prefent courfe will be nearly four points.

Secandly, in fig. \(\hat{3}\). if F , by carrying more \{ail, move at the rate of fix miles an hour, from \(F\) to \(G\), then \(P\), with a more flanting courfe, will have more dilficulty in keepiner the line a-breatt while coming down to the allach, owing to the additional obftruction which will attend each fucceeding thip in fuch a llanting courfe. Arain, if the leeward neet thall lie thp one point higher, as FG , fig. 4. the rears of the two fleets will be removed to a much greater diflance, and the van \(A\) mult be fooner up with the encmy's van, and of courfe fo much farther from cupport, while \(F\) bringing up his flups in fucceflion, may difable the van of \(A\), and afterwards bear away at pleafure with little injury, as at H. Now A being fuppofed difabled, and having his rear D difracted, will be unable to prevent F from efcaping.

From thefe confiderations it appears that a fleet to windward, by extending its line of battle with a view to Rop and attack the whole line of an enemy's feet to leeward, muft labour under confiderable difadvantages, and will fcarcely fucceed in the attempt.

On thefe principles Mr Clerk explains the reafon why, before the commencement of the prefent conteft between Britain and France, the French fleets fo repeatedly efcaped from the Britifh, without any ferious defeat or lofs, viz. by avoiding a general engagement, and difabling the Britill van as it bore down to attack them. He therefore recommends a different mode of attack from the windward, which we thall proceed to illuftrate by proper diagrams.

Let \(F\) (fig. 5.) reprefent a fleet in line of battle, under eafy fail, willing to avoid an action, but ready to receive an attack in the ufual way, from another flect B, three or four miles to windward, arranged in three columns. How fhall B make the attack on F , fo as, without aiming at the improbable advantage of taking or deftroying the greater part of this fleet, they may fecure three or four of the fiernmon thips? Mr Clerk advifes, that a fufficient frength be detached to fecure thefe flips, while the admiral keeps aloof with the reft of his fleet, difpofed as in the figure, ready to make the neceffary oblervations and give the requifite fupport to the detached Gips. If F continnes to avoid an action by flanding on in line, the detachment. coming into the pofition BA, will fecure the three fhips at I; and if the headmolt hips of \(F\) were to tack, and be followed by the reft in fucceflion as at fig. 6. not only the three fhips at I will be left at the mercy of the flips detached from B , but two more, as G , will be expofed to an attack from another fquadron of B at C . If all the fhips of F tack together, as in fig. 7 . the delay, and probably the confufion, conifquent on this manouvre, will fill more endanger the fernmoft Atips, or will bring on a general and clofe action. Again, if \(F\) attempts to haul off, beginning with his fternmoft thip \(G\), . 8. and and then runs to leeward, as at fig. 8. he will expofe his thips to a raking fie from \(B\), and ftill endanger his fernmof finips by getting too far to leeward for their fupport ; or if the headmoft thips at H, fig. 9. veer Grft, to be followed by the reft aftern, the danger would be ftill greater. Thus it appears that in every alfignable

A R.
cale, a fleet to leeward, avoiding an attack: from an equal or fuperior windward, as here advifed, by preferving the
line, will rill the lefs of threc or more of their tlernmoll Thips.

Now, let us fuppofe that \(F\), while ftanding on in rig. 10,11 , line on the larboard tack, when threatened with an at- 12 . tack on his rear from l , vecrs and paffes on oppofte tacks to leeward (lee fig, 10.). The confequence of this will be, that his headmult nips will be furced to leewasd hy \(P\), and compelled to engage under difadvantageous circumfances, and the difadvantage to F will be much the fame, whother he again veers and refumes his former pofition, as at \(G\), fig. if. or flands on before the wind, as at P, fig. 12.

We have hitherto fuppofed that the wind has been rig. 13. gived in one point; but let us fuppofe it to hift, and let us inquire what will be the effect of fuch a circunflance on the two lines F and B . While the fleets are in the former pofition, \(F\) in line, and \(B\) in four divifions \(B, B, B, A\), ftecring \(E\), with the wind at \(N\), fig. 13. let the wind fhift to the welt. The only confequence of this will be, that \(F\) will be thrown flill farther to leeward, to its greater difadvantage. But let the wind thift to E, fo as to be a-head, as in figs. I4. Figs. I4, and 15 . Still if the admiral of \(B\) manages properly, and 15. and carefully watches the motions of \(F\), this change will produce no advantage to the latter. For B has nothing to do but veer as the wind comes round, fo as to bring his mips to windward of the three flernmoft mips of \(F\), and to leeward of the reft of his line, fu as to cut off the three flernmof flips.

If the wind Mould be fuppofed to veer from point to point all round the compafs, fo that the fleet F , maintaining the weather-gage of \(B\), hall make a circuit round B to leeward; ftill if B ast cautioufly, F will lofe the three threatened hips.

Laftly, fuppof the wind fhould intantly Mift to a Fig. 16. point oppofite to what it was at the commencement of the attack, as from N. to S. Before it can be afcertained whether fuch a change will be to the advantage or difadvantage of \(F\), the relative fituations of the two fleets muft be confidered. Suppofe that the van and centre be feparated at fome diftance from his rear, and that in confequence this fleet fuall have taken fuch a pofition as is fhown at fig. 16. Though in this cafe be Fig. 16. will have got to windward, his three hips can never be regained or preferved from the attack of P. The moft favourable fituation for F would be when the flecis were in the pofition denoted by fig. 13. as then lie could not only fupport his three hips with advantage, but even threaten, and cut off a part of B 's detachment. In attempting this, however, he incurs the rift of coming to a clofe engagement, which we have fuppofed lim to be feduloully avoiding.

Belides this method of altack from the windwand by From the detachments from the main fleet, Mr Cierk thows how leeward. a fuccefsful attack may be made by a fect to leeward, by its breaking the enemy's line, and this cither near the rear, near the centre, or not far from the van, of which cales the two former will be moft likely to prove fuccefsful. The cnemy's line can bc cut only when the two lootile feets veer on appofite tacks. The mof fimple method or effecting this is for the van fhip of the attacking fquadron, inftead of ranging parallel to that of the enemy, and to leeward of lim, to pals through

N’aval Tactics.
the firf interval that offers, followed by the seft of the line, which is thus led acrofs that of the enemy. In confequence of this manoeuvre, the van of the leeward fleet will be to windwatd of the enemy's rear, and thus the attacking fquadron will have its line entire, while that of its adverfary is divided. Again, the fhips of the rear divifion, having therr progrefs obtructed, will probably crowd on each nther, get into confufion, and be driven to leeward. We cannot detail the different cafis mentinned by Mr Clerk; but for thefe and many other valuable fuggeftions on the fubject of naval tactics, we mult refer to his utelul and ingenious Eltay *.

The above is a very faint and meagre outline of Mr Clerk's tactics, but it is all which our limits eable us to give. It will afford general readers fome idea of the rature of the propofed improvements, and profeflional men will naturally confult the original effay.

On thefe or dimilar principles is founded the method of breaking through the enemy's line, and thus cutting off a part of his fleet, fo fuccefffilly adopted by the Buitifh admirals in the great naval actions that have diftinguifhed the late and picfent wars with France. We cannot better illufrate the principles above laid down, than by giving a flort detail of the laft of thefe memorable engagements, the Battle of Trafalgar. With this wee fhall conclude our feetch of naval tantics, and our practical obfervations on the art of War.
After having been long blocked up in the harbour of Cadiz, the combined Frencla and Spanith fleet effected their efcape, while the Britifh fleet, under the com- mand of Lord Nellon, was at a confiderable diflance. On the 19th of October 1805 , the flips which had been left to watch the motions of the enemy, communicated to the commander in chief the agreeable intelligence, that the combined fleet had put to fea, and was faiising with light winds in a wefterly direction. Lord Nelfon concluding that their dellination mufl be the Mediterranean, immediately made all fail with his hhips for the entrance of the firaits. Here he was informed by Captain Blackwood, that the eneny had not yet paffied the fraits.

On the zuft of October, at daylight, Cape Trafalgar bearing eaft by fouth about feven leagues diffant, the combined fleet was difcovered about fix or feven miles to the eaftward. The wind was about weft, and very light. As Lord Nelfon had long expected to fall in with the enemv's fleet, he had concerted with his officers the belt and moft expediticus meafures for bringing them to a fpeedy and decilive action. As foon, therefore, as they hove in fight, he immediatcly made the fignal for the Britilh ficet to benr up in two columns, as thicy formed in order of failing. The combined fleet was drawn up in line of batte, with their l.eads in the nothward, and had formed the line with great clofenefs and correenefs. It confitted of 33 thips of the line, 18 French, and 15 Spanith, under Admiral Villeneuve, as commander in chief, who orcupied the centre in the Bucentaure, while the Spanih admiral, Gravina, led the rear in the Prince of Afturias. The Brition fleet confifed of 27 fline, including three fislyfours. Lord ivelfon headed the van in the Vifory,
having under !om the Temeraise, Neptune, Cunqueror, Leviathan, Ajax, Orion, Agamemnon, Minotzur, Sjartinte, Bitannia, Africa, with the Euryalus, Sirius, Ithowe, and Naiad frigates, Pickie fchouner, and Entreprenante cutter; while the rear, confilling of the hoyal Sovereign, Mars, Peileill, 1 onnant, Belleroo phon, Colofius, Achalle, l'olyphemus, hevengc, Swiftfure, Defence, Thunderer, Defiance, Prince, and Ditadnought, was led by Vice-admital Coling wood in the Royal Suvercizn.

As the mode of attack adnpted by the Britifh was unufual, the combined fleet was obliged to diaw up their line in a new manser. It formed a crefeent, with its convexity to leeward, fo that in leading down to their centre, the rear divifion of the Britith had both their van and rear abaft the beans. Betore the action commenced, every alternate flip was abcut a cable's length to windward of her fecond ahead and aftern, thus forming a kind of double line, and appearing, when on their beam, to leave a fmall interval betrucen them without crowding their thips. The French and Spaniards were not tormed in feparate divifions, but intermixed without any apparent regard to order of national fquadrons. As the Bitifif commander had previoufly communicated to his flag-officers and captains his pre-concerted mode of attack, few fignals were nece!fary, and none were made on approaching the enema, except to direet clofe order as the lines bore down.

The action commenced at noort, by the leading fhips of both columns, breaking through the encmy's line, the Victory about the tenth hip from the vas, and the Royal Sovereign about the tweifth from the rear; the fucceeding fhips breaking through in every part aftern of their leaders, and engaging the enemy at the rery muzzles of their guns. By this marceuvre the wan of the enemy was unengaged, and thus the inferiority of the Britih, in point of number, was of \(\}\) fe confequence, while the fuperior ikill and bravery of Britifh feamen foon acquired a decided advantage. The conflict was fevere, as the encmy's hilips were furght with a gallantry highly honourable to their commanders. The Britifh attack, however, was irrefitible. About three P. M. many of the enemy's fhips had Aruck their colours, and their line had given way. Ten thips of the line, and the frigates, under Almiral Gravina, made. their efcape, and flood to leeward towaro's Cadiz. The five headmof fhips of their wan tacked. and. fanding to the fouthward, to windward of the Britifh line, were brought to action, and the fternmolt of them taken. Nineteen flips of the line, with three flag-officers, including the commander in chief, remained in the hands of the Britill. Never was theie a victory more glorious or more decilive; ncver was the preeminence of the Britifl flag more triumphantly cunficicuous.

The even!s fubrequent to this memorable hat le, and the loifes fullained on either fite, having little connection with the fubje t of the prefent article, need not be here detailed. They are fief in the memory of our readers, and Buitain flill laments the lofs of her immor. tal Nelfon".

Wax Man-of-War Bird. See Pelrcanus, Ornitholoay Index.
Wdil-Cry was formerly cultomary in the armies of moft nations, when jult upon the point of engaging. Sometimes they were only tumultuous fhouts, or horrid yells, uttered with an intent to Itrike terror into their adverfaries; fuch as is now ufed by the Indians in \(\Lambda\) merica, called the war-whoop.

WARBLES, a difeafe of horfes, fee Farkiery Index.

Warburton, Willian, a learned Englifh biflop, was defcended from an ancient family in Chehire, and was the fecond fon of George Warburton, an attorney at Newark in the county of Nottingham, was born at Newark, December 24. 1698. He was firft put to fcliool there under a Mr Twells, but had the chief part of his education at Okeham in Rutlandllhire, where he continued till the beginning of the year 1714, and foon after he was put out clerk to an eminent attorney of Great Markham in Nottinghamflire, where he continued till the year 1719, when he returned to his family at Newark ; but whether he practifed there or elfewhere as an attorney, is not known.

He had always expreffed a flrong inclination to take orders; and the love of letters, which tended to retard, rather than forward, his progrefs in the profefiion chofen for him by his friends, growing every day ftronger in him, it was deemed expedient to give way to that inclination. He therefore devoted himfelf to the fudies neceffary to fit him for the church, and at length in 1723 he was ordained deacon, and prieft in 1727.

In 1728 he was prefented by Sir Robert Sutton to the rectory of Brand-Broughton, in the diocefe of Lincoln, where he fpent the greater part of his life, and compofed all the great works which will carry his fame down to pofterity. In the fame year he was put upon the king's lift of Mafters of Arts, erected on his majefty's vifit to the univerfity of Cambridgc. He had already publifhed fome juvenile performances, which difplayed genius and reading, and attracted confiderable notice; but it was not till the year 1736 that he may be faid to have emerged from the obfcurity of a private life into the notice of the world.-The firft publication which rendered hins afterwards famous now appeared, under the title of "The Alliance between Church and State ; or, the Neceflity and Equity of an Eftablifhed Religion and a Teft Law ; demonftrated from the Effence and End of Civil Society, upon the fundamental Principles of the Lavr of Nature and Nations." In *Revicw of this treatife, fays Bifhop Horftey*, the author "hath be Cafe of thown the general good policy of an eftablinhment, and he Protetant Dif. ienters, Lond. 1757. Preface. the neceffity of a Test for its fecurity, upon principles which republicans themfelves cannot eafily deny. His work is one of the finelt fpecimens that are to be found perhaps in any language, of fcientific reafoning applied to a political fubject."

At the clofe of the Alliance was announced the fcheme of the Divine Legation of Mofes, in which he had then made confiderable progrefs. The firt volume of this work was publifhed in Jannary 1737-8, under the title of "The Divine Legatinn of Mofes demonftrated on the Principles of a religious Deif, from the Omiffion of the Doctrine of a future State of Rewards and Punifhments in the Jewith Difpenfation, in fix books, by William Warburton, M. A. author of Vol. XX. Part II.
the Alliance between Church and State;" and met Warburton. with a reception which neither the fubject, nor the manner in which it was treated, feemed to aullorile. It was, as the author afterwards obferved, fallen upon in fo outrageous and brutal a manner as had been fcarce pardonable, had it becn "The Divine Legation of Ma-homet."-It produced feveral anfwers, anid \(f_{0}\) much abufe from the authors of "The Weekly Mitcellany," that in lefs than two montlis he was conll rained to defend himfelf, in " A Vindication of the Author of the Divine Legation of Mofes, from the Afperfions of the Country Clergyman's Letter in the Weekly Mifcellany of February 24. 1737-8, 8 vo."

Mr Warburton's extraordinary merit had now attracted the notice of the heir apparent to the crown, in whofe immediate fervice we find him in June : \(73^{8}\), when he publifhed "Faith working by Charity to Chriftian Edification, a Sermon, nreached at the laft epifcopal Vifitation for Corfirmation in the Diocefe of Lincoln; with a Preface, flowing the licafon of its Publication; and a Pofficript, occafioned by fome Letters lately publifhed in the Weekly Mifcellany; by William Warburton M. A. Chaplain to his Royal Highnefs the Prince of Wales."

The "Eflay on Man" had now been publilined fome years; and it is univerfally fuppofed, that the author had, in the compofition of it, adopted the philofophy of Lord Bolingbroke, whom, on this occafion, he had followed as his guide, withont underitanding the tendency of his principles. In 1738, M. de Croufaz wrote fome remarks on it, accufing the author of Spinazifm and \(\mathrm{Na}-\) turalifm ; which falling into Mr Warburton's hands, he publifhed a defence of the firt epifte, and foon after of the remaining three, in feven letters; of which fix were printed in 1739, and the feventh in June 1740, under the title of "A Vindication of Mr Pope's Eflay on Man, by the author of the Divine Legation." The opinion which Mr Pope conceived of thefe defences, as well as of their author, will be beff feen in his letters. In confequence, a firm friendihip was eftablifted between them, which continued with undiminifhed fervour until the death of Mr Pope; who, during the remainder of his life, paid a deference and refpect to his friend's judgement and abilities, which will be conlidered by many as almof bordering on fervility.

Towards the end of the year 1739, Mr Warburton publifhed a new and improved edition of the firt volume of the Divine Legation; and in 1741 , appeared the fecond part, which completed the argument, though not the entire plan of that work. "A work, Cays Bifhop Hurd *, in all views of the mott tranfcendant * Life of merit, whether we confider the invention or thc execu-Warburton tion. A plain fimple argument, yet perfectly new. prefface to proving the divinity of the Mofaic law, and laying a fure foundation for the fupport of Chrifinanity, is there drawn out to a great length by a chain of reafoning fo elegantly connected, that the reader is carried along it with eafe and pleafure; while the matter prefented to him is fo friking for its own importance, fo embellifhed by a lively fancy, and illufitrated from all quarters by exquifite learning and the moft ingenious difquifition, that in the whole compafs of modern or ancient theology, there is nothing equal or fimilar to this extraordinary performance."
- This is the panegyric of a man reflecting with ten\& L dernefs

\section*{W A R [ 63t ] W A R}

Warberton. dernefs on the memory of his friend and benefastor; but it approaches much nearer to the truth than the cenfures of thofe cabaliftic critics, who, fatlening upon fome weak part of the Divine Legation, or perlaps never having looked into it, have ridiculoufly contended that the author was far from being eminent as a fcholar, and that his work is inmical to the caufe of Chriftianity! Putting partiality afide, there is in the Divine Legation of Mofes abundant evidence of the malignant folly of this charge, as no man can read and underitand that work without being convinced that its author was a Chifition, not only fincere but zealous; that he was,
*Life of
Pope. what Johnfon calls him *, "a man of vigorous faculties, of a mind fervent and vehement, fupplied, by unlimited and inceffant inquiry, with a wonderful extent and variety of knowledge, which had neither deprefied his imagination nor clouded his perfpicuity; and that to every work, and this work in particular, he brought a mencry full fraught, with a fancy fertile of original combinations, exerting at once the powers of the fcholar, the reafoner, and the wit." But we think it mult be acknowledged, that his learning was too multifarious to be always exact, and his inquiries too eagerly puined to be always cautious. We have no hefitation, however, to fay, that io the divine this great work, with all its imperfections, is, in our opinion, one of the molt valuable that is to be found in any language.

In the fummer 1741, Mr Pope and Mr Warburton, in a country ramble, took Osford in their way. The univerfity was naturally pleafed at the arrival of two fuch frangers, and feemed defirous of enrolling their names among their graduates. The degree of D. D. was intended for the divine, and that of LL. D. for the poet : but intrigue and envy defeated this fcheme; and the univerfity loft the honour of decorating at the fame time the two greatell geniufts of the age, by the fault of one or two of its members. Pope retired with fome indignation to Twickenham, where he confoled himfelf and his friend with this fatcallic reflection"We thall take our degree together in fame, whatever we do at the univerfity."

The friendihip of this eminent paet was of fervice to Mr Warburton in more refpects than that of increafing his fame. He introduced and warmly recommended him to molt of his friends, and among others to Mr Murray, afterwards earl of Minsfield, and Ralph Al. len, Efq. of Prior-park. In confequence of this introduction, we find Mr Warburton at Bath 1742 ; where lee printed a fermon which had been preached at the Abbey-church on the \(24^{\text {th }}\) of October, for the benefit of Mr Allen's favourite Charity, the General Hofpital or Infirmary! In this year alfo be printed a Differta. tion on the origin of books of chivalry, at the end of Jurvis's Preface to a Iranlation of Don Quixote, which Mr Pope tells him, he had not got over two parasraphs of, before he cried out, Aut Erafmus, aut Diabolus.

In 1742, Mr Warluurton publiplied "A Critical and Philofophical Commentarv on Mr Pope's Effay on Man, in which is contained a Vindication of the faid Effay from the Mifreprefentation of M. de Refnal, the Frencls Tranlitor, and of M. de Croufaz, Profeflor of Philofophy and Mathematics in the Academy of Laufanne, the Commentator." It was at this perind, when Mr Warburton had the entire confidence of Mr Pope; that
he advifed him to complete the Dunciad, by ckanging yrarbur the hero, and adding to it a fourth book. This yas accordingly executed in 1742, and publihed early in 1743, with notes by our author ; who, in coufequence ot 11 , jeceived his hate of the abule which Mr Clbljer liberally beftowed on both Mr Pupe and his annotator. In the latter end of the fame yeat he publithed complete editions of "The Eflay on Nan," and "1 he Effay on Criticim;" and from the feecimen which be these exhibited of his abilities, it may be prefumed Mr Pupe determined to commit the publication of thofe works which he fhould leave to Mr Warourton's care. At Mr Pope's defire, he, about this time, revifed and corrected the "Eflay on Homer," as it nuw Itands in the lalt edition of that tranflation.

The publication of "Ihe Dunciad" was the laft fervice which our author rendered Mr Pope in his litetime. After a lingering and tedious illnefs, the event of which had been long forefeen, this great fost died on the 30 th of May 1744 ; and by lis will, dated the \(12 \mathrm{ll}^{\text {ot }}\) the preceding December, bequeathed to Mr Warburton one half of his library, and the property of all fuch of his works already prinied as he liad not otherwife difpofed of or alienated, and all the profits which hould arife from any edition to be printed after his death : but at the fame time direfted that they fhould be publithed without any future alterations.
"In 1744, Mr Warburton turned his attention to the feveral attacks which had been made on the "Divine Legation," and defended himfelf in a manner which, if it did not prove him to be poffeffed of much humility or diffidence, at leaft demonftrated, that he knew how to wield the weapons of controverfy with the hand of a mafter. His firt defence now appeared, under the title of "Remarks on feveral oceafional Retiec. tions, in Anfuer to the Reverend Dr Middleton, Dr Pococke, the Mafter of the Cliarter-Houic, Dr Richard Grey, and others; ferving to explain and junify divers Paflages in the Divine Legation, objecied to by thofe Icarned Writers. To which is added, A General Review of the Argument of the Divine Legation, as far as it is yet advanced; wherein is confidered the Relation the feveral Parts bear to each other and tho wbole. Together with an Appendix, in Anfwer to a late Pamphlet intitled, An Examination of \(\mathrm{Mr} \mathrm{W} \longrightarrow\) _s fecond Propobtion." This was followed next year by " Remarks on feveral occafional Reflection, in Anfwer to the Reverend Doctors Srebbing and Sykes; ferving to explain and juftify the Two Diflertations in the Divine legation, concerning the Command to Abralam to offer up his Son, and the Nature of the Jewifh Theocracy, ubjected to by thefe learned Writers. Part II. and lant." Both thefe anfwers are couched in thofe high terms of corfident fuperiority, which marked almof every performance that fell from his pen during the remainder of his life.

On the \(5^{\text {th }}\) of September 1775 , the friendithip between him and Mr Allen was more clofely cemented by his marriage with. Mifs Tucker, who furvived, and is now, if alive, Mrs Stafford Smith of Prior-park. At that important crifis our author preached and publillied three feafonable fermous: 1. "A fathful Portrait of Popery, by which it is feen to be the lleverfe of Chriftianity, as it is the Deftruction of Morality, Piety, and Civil Liberty. Pieached at St James's, Wefminfter,

Oteber
 préfent unnataral Rebellion, \&ic. Preached in Mr Allen's Chapel at Prior-park, near Bath,'November 1745." 3. "The Nature of National Offences truly ftated. Ireached on the General Fall-day, Dec. 18. \(17+5\)-6." On account of the laft of thefe fermons, he was again involved in a controverfy with his former antagonift \(\mathrm{Dr}_{r}\) Stebbing, which occafioned "An Apologetical Dedication to the Reverend Dr Henry Stebbing, in Anfwer to his Cenfure and Mifreprefentations of the Sermon preached on the General Fait, \&c."

Notwithtanding his great connections, his acknowledged abilities, and his eftablified reputation, a reputaton founded on the durable batis of learning, and upheld by the decent and attentive performance of every duty incident to his fation; yet we do not find that he xeceived any addition to the preferments given hins in 1728 by Sir Robert Sutton (except the chaplainflip to the prince of Wales), until April 1746, when he was unanimoufly called by the Society of Lincoln's Inn to be their preacher. In November he publilhed "A Sermon preached on the Thanfgiving appointed to be obferved the \(9^{\text {th }}\) of OGober, for the Supprefion of the late unnatural Rebellion." In 1747 appeared his edition of Shakefpeare and bis Preface to Clariffa; and in the fame year he publifhed, 1. "A Letter from an Author to a Member of Parliament concerning Literary Property." 2. "Preface to Mrs Cockhurn's Remarks upon the Principles and Reafonings of Dr Rutherford's Effay on the Nature and Obligations of Virtue, \&c." 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Philofophers, concerning the Nature of a Future State, and their Method of teaching by double Doetrine," (by Mr Towne) 1747, fecond edition. In 1748 , a third edition of "The Alliance between Church and State, corrected and enlarged."
" In 1749, a very extraordinary attack was made on the moral chatacter of Mr Pope, from a quarter where it could be leaft expected. An infignificant pamphlet, under the name of A Patriot King, was that year publified by Lord Bolingbroke, or by his direction, with a preface to it, reflecting highly on Mr Pope's honour. The provocation was fimply this: The manufeript of that trivial declamation had been intrufted to the care of Mr Pope, with the charge (as it was pretended) that only a certain number of copies flould be printed. Mr Pope, in his exceffive admiration of his guide, phizofo. plier, and friend; took that opportunity, for fear fo insvaluable a treafure of patriot eloquence fhould be lof to the public, to exceed his commiltion, and to run off more copies, which were found, after his death, in the printer's warehoufe. This charge, however frivolous, was aggravated bevond meafure; and, notwithflanding the proofs which Lord Bolingbroke had received of Yope's devotion to him, envenomed with the utmoft malignity. Mr Warburton thought it became him 10 viadicate his deceafed friend; and he did it fo effectually, as not only to filence his accufer, but to covet him with
fion Mr Waburton publiflied an excellent perfotmance, Wauburixto written with a degree of candour and temper, which, it is to be lamented, he did not always exescife. 'Jhe title of it was "Julian; or a Difcourle concerning the Earthquake and fiery Eruption which defeated that Einuperur's attempt to rebuild the 'Temple at Jerwalen, \(1750 . "\) A fecond edition of this difcourfe, "with Additiuns," appeared in 1751, in which year he gave the public his edition of Mr 1'ope's Works, with Notes, in nine vulumes 8 vo; and in the fane year pritited "An Anfuer to a I.etter to Dr Middleton, interted in a Pamphlet intitled, The Argument of the Divine leegation fairly flated," \&c.; and "An Account o: the Propliecies of Aife Evans, the Welfi Propliet in the latt Century," annexed to the firt volume of Dr Jurtin's Remarks on licelefiallical Hittory, which afterwards fubjested him to much trouble.

In 1752, Mr Warburton publifhed the firf volume of a courfe of fermons, preached at Lincoln's Inn, intitted, "The Principles of Natural and Revealed lieligion, occafinnally opened and explained;" and this sas two years afterwards followed by a fecond. After the public had been fome time piomifed, it may, fiom the alarm which was taken, be almof faid threatened with, the appearance of Lord Bolinghroke's Woaks, they were about this time printed. The krown abilities and infidelity of this noblem:n had created apprehenfions in the minds of many pcople, of the pe:nicious effects ot his doclrines; and nothing but the arpearance of his whole force could have convinced his friends, how little there was to be dreaded from arguments ag.init reigion fo weakly fupported. Many anfwers were foon publifhed, but mone with more acutenefs, folidity, and iprightlinefs, than " A View of Lord Bolingbroke's Philulophy, in two Letters to a Friend, \(1754 ;\) " the third and fourth letters were publimed in 1755 , with another edition of the two former; and in the fame year a fmaller edition of the whole; which, though it came into the world without a name, was univerfally afcribed to Mr Warburton, and afterwards publicly owned by him. To fome copies of this is prefixed an excellent complimentary epillle from the prefident Montefquieu, dated May 26. 1754.

At this advanced perind of his life, that preferment which his abilities might have clamed, and which had hitherto been withheld, feemed to be approaching towards him. In Septernher if54, he was appointed one of his majelly's chaplains in ordinary; and in the next year was prefented to a prebend in the cathedral of Durham. Ahout this time the degree of Doctor of Divinity was conferred on him by Dr Herring, then archbifhop of Canterbury. A new impreflion of The Divine I.egation being now called for, he printed a fourtin edition of the firft part of it, corrected and enlarged, divided into two volumes, with a dedication to the earl of Hardwicke. The fame year appeared "A Smon preached before his Grace Charles Duke of Marlborough, Prefident, and the Governors of the Hofpital for the Smallpox and for Inoculation; at the Parithcharch of St Andrew, Holborn. April the 24 h, 1755 ." And in 1756, Natural and Civil Events the Infru. ments of God's Moral Government ; a Sermon, preached on the laft public Faft-day, at-Lincoln's Inn Chapel.s"
if In 1757, Dr Warburton meeting with Mr Fumn's
4 I. 2
tract,

\section*{W A R \(\quad\left[\begin{array}{lll}63 & ]\end{array}\right] \quad\) W \(\mathbf{R}\)}

Warburton tract, entitled, The Natural Hiftory of Religion, filled the margin of the book, as well as fome interleaved nips of paper, with many fevere and Chrewd remarks on the infidelity and naturalifm of the author. Thele he put into the hands of his friend Dr Hurd, who, making a few alterations of the fiyle, added a thort introduction and ennclufion, and publifhed them in a pamphlet, entitled, "Hemarks on Mr David Hume's Natural Hittory of Religion, by a Gentleman of Cambridge, in a Letter to the Reverend Dr Warburton." This lively attack upon Mr Hume gave him fo much offence, that he thought proper to vent his fplcen on the fuppofed author, in the polthumous difcourfe which he called his Life; and thus to do greater honour to Dr Hurd than to any other of his numerous antagonifts.

Towards the end of the year 1757, Dr Warburton was promoted to the deanery of Brittol ; and in the beginning of the year \(1^{17} 60\), he was, through Mr Allen's interelt with Mr Pitt, afterwards earl of \(C^{\circ}\).atham, advanced to the bilhopric of Gloucefter. That great minifler is known to have declared, " that nothing of a private nature, fince he had been in office, had given him fo much pleafure as bringing our author on the bench." There was, however, another minilter, who dreaded his promotion, and thought he faw a fecond Atterbury in the new bihhop of Gloucefter; but Warburton, fays Bithop Hurd, had neither talents nor inclination for parliamentary intrigue or parliamentary eloquence : he had other inftrumeats of fame in his hands, and was infinitely above the vanity of being caught
* Dryden.
"With the fine notion of a bufy man *."
He-was confecrated on the 20th of January 1760 , and on the 30 th of the fame month preached before the houle of lords. In the next year he printed "A Rational Account of the Nature and End of the Sacrament of the Lord's Supper." In 1762, he publithed "The Doctrine of Grace; or the Office and Operations of the Holy Spirit vindicated from the Infults of Infidelity and the Abufes of Fanaticifm, 2 vols 12 mo ; and in the fucceeding year drew upon himfelf much illiberal abufe from fome writers of the popular party, on occafion of his complaint in the houfe of lords, on the 15 th of November 1763, againf Mr Wilkes, for putting his name to certain notes on the infamous "Effay on Woman."

In 1765 he publifhed a new edition of the fecond part of the Divine Legation, in three volumes; and as it had now received his laft hand, he prefented it to his great friend Lord Mansfield, in a dedication which deferves to be read by every perfon who efteems the wellbeing of fociety as a concern of any importance. It was the appendix to this edition which produced the wellknown controverfy hetween him and Dr Lowth, which we have noticed elfewhere (fee Lowth), as doing no great honour, by the mode in which it was conducted, to either party. In the next year he gave a new and much improved edition of the Alliance between the Church and State. This was followed, in 1767 , by a third volume of fermons, to which is added, his firft Triemial Charge to the Clergy of the Diocefe of Glouceffer; which may be fafely pronounced one of the moft valuable difcourfes of the kind that is to be found in our own or any other language. With this publication he clofed his literary cousfe; except that he made an
effort towards publifhing, and actually printed, the ninth Warburu and laft book of the Divine Legation. This book, with Ward one or two occafional fermons, and fome valuable direct tions for the tludy of theology, have been given to the world in the fplendid edition of his works in feven volumes 4 to, by his friend and biographer the prefent bifhop of Worcetler. 'Hat prelate confeffes, that the ninth book of the Divine Legation difplays little of that vigour of mind and fertility of invention which appear fo confpicuous in the former volumes; but he adds, perhaps truly, that under all the difadvantages with which it appears, it is the nobleft effort which has hitherto been made to give a rationale of Chriftianity.

While the bifhop of Gloucefter was thus exerting his laft Itrength in the caufe of religion, he projected a method by which he hoped to render it effectual fervice after his death. He transferred 5001 . to Lord Mansfield, Sir Eardley Wilmot, and Mr Charles Yorke, upon truft, to found a lecture, in the form of a courfe of fermons, to prove the truth of revealed religion in general, and of the Chriftian in particular, from the completion of the prophecies in the Old and New Teftament, which relate to the Chrillian church, efpecialiy to the apoftacy of Papal Rome. To this foundation we owe the admirable Introductory Leetures of Hurd, and the well-adapted Continuation of Halifax and Bagot.

It is a melancholy reflection, that a life feent in the conftant purfuit of knowledge, frequently terminates in the lofs of thofe powers, the cultivation and improvement of which are attended to with too ftrict and unabated a degree of ardour. This was the cafe with \(\mathrm{Dr}_{\mathrm{r}}\) Warburton; and it feems probable that this decline of intellectual vigour was aggravated by the lofs of his only fon, a promifing young man, who died of a confumption but a fhort time before the bifhop, who himfelf refigned to fate in the year 1779 , and in the 81ft of his age. A neat marble monument was erected to his memory in the cathedral of Gloucetter.

WARD, Dr Seth, an Englifh prelate, chiefly diflinguifhed for his knowledge in mathematics and aftronomy, was born at Buntingford in Hertfordfhire, about the year 16ı7. He was admitted of Sidney college, Cambridge, where he applied with great vigour to his ftudies, particularly to the mathematics, and was chofen fellow of his college. He was much involved in the confequences of the civil war, but foon after the Reftoration obtained the bihopric of Exeter; in 1667 , he was tranflated to Salifury; and in 1671 was made chancellor of the order of the garter; lie was the firft Proteftant bilhop that enjoyed that honour, and he procured it to be annexed to the fee of Salibury. Biftiop Ward was one of thofe unhappy perfons who have the misfortune to furvive their fenles, which happened in confequence of a fever ill cured; be lived to the Revolution, without knowing any thing of the matter, and died in 1690. He was the author of feveral Latin works in mathematics and aftronomy, which were thought excellent in their day; but their ufe has been fuperfeded by later difcoveries and the Newtonian philofophy.

WARD, is varioufly ufed in our old books : a ward in London is a diftrict or divifion of the city, commit. ted to the fipecial charge of one of the aldermen; and in London there are 26 wards; according to the number of the mayor and aldermen, of which every one has
dhudd his ward for his proper guard and junifdiction. \(A\) fo. \(\sqrt{3 \text { and }}\) reft is divided into wards; and a priton is called a ward. Laftly, the heir of the king's tenaut; that held in capile, was termed a ward during his nonage; but this wardthip is taken away by the itatute 12 Car. II. c. 24 .

Wakd-Holding, in Scots Law. See Laiw, N \({ }^{\text {o }}\) elxv. I. and clxvi. 3 .
j WARD-Hook, or Wadd-liook, in Gunncry, a rod or flaff, with an iron end turned ferpentwife, or like a ferew, to draw the wadding out of a gun when it is to be unloaded.
WARDEN, or Guardian, one who has the charge or keeping of any perfon, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet prifon; who has the charge of the prifoners there, efipecially fuch as are committed from the court of chancery for contempt.
WARDHUYS, a port of Norwegian Lapland, 120 miles fouth-eaf of the North Cape. E. Long. 3I. 12. N. Lat. 70. 23.

WARDMOTE, in London, is a court fo called, which is kept in every ward of the city; anfivering to the curiata comitia of Rome.

WARDROBE, a clofet or little room adjoining to a bedchamber, ferving to difpofe and keep a perfon's apparel in ; or for a fervant to lodge in, to be at hand to wait, \&c.

Wardrobe, in a prince's court, is an apartment wherein his robes, wearing apparel, and other neceflaries, are preferved under the care and direction of proper officers.

In Britain, the Maffer or Keeper of the Great Wardrobe was an officer of great antiquity and dignity. High privileges and immunities were conferred on him by King Henry VI. which were confirmed by his fucceflors; and King James I. not only enlarged them, but ordained that this office fhould be a corporation or body politic for ever.
It was the duty of this office to provide robes for the coronations, marriages, and funerals of the royal family; to furnifh the court with hangings, cloths of fate, carpets, beds, and other neceflaries; to furnilh houfes for ambaffadors at their firft arrival ; cloths of ftate, and other furniture, for the lord lientenant of Ireland, and all his majefly's ambafladors abroad; to provide all robes for foreign kuights of the garter, robes for the knights of the garter at home; robes and all other furniture for the officers of the garter ; coats for kings, heralds, and purfuivants at arms; robes for the lords of the treafury, and chancellor of the exchequer, \&c.; 1ivery for the lord chamberlain, grooms of his majefty's privy chamber, officers of his majefty's robes; for the two chief juftices, for all the barons of the excluequer, and feveral officers of thefe courts; all liveries for his majefty's fervants, as yeomen of the guard, and wardens of the Tower, trumpeters, kette-drummers, and fifes; the meffengers, and all belonging to the fables, as coachmen, footmen, littermen, poffilions, and grooms, \&cc. all the king's coaches, chariots, harnefles, faddles, bits, bridles, \&c. the king's watermen, game-keepers, \&cc. alfo furniture for the royal yachts, and all rich \(\in \mathrm{m}\) broidered tilts, and other furniture for the barges.

Befides the mafter or keeper of the wardrobe, who had a falary of 20001 . there was his deputy, who had 1501. and a comptroller and a patent clerk, each of
whom has a falary of 300 . Befides many other infe- Wardroise rior ofticers and fervants, who were all fworn fervants Wardhip. to the king.

There was likewife a removing wardrobe, who had its own fet of officers, and ftanding wandrobe-keepers at St James's, Windfor Callle, Hampton Court, Kenfington, and Somerfet Houfe ; but the whole of the wardrobe eltabliflument was abulifhed by act of parliament in 1782 , and the duty of it in future to be dune by the lord chamberlail.

WARDSHIP, in chivalry, one of the incidents of tenure by knight-fervice. See Feodal System, KNIGHT Service, and Tenure.

Upon the death of a tenant, if the heir was under the age of 21 , being a male, or 14 , being a female, the lord was intitled to the wardllip of the heir, and was called the guardian in chivalry. This wardfhip confifted in having the cuftody of the body and lands of fuch heir, without any account of the profits, till the age of 21 in males, and 16 in females. For the law fuppofed the heir-male unable to perform knight-fervice till 21 ; but as for the female, fhe was fuppoied capable at 14 to marry, and then her hufland might perform the fervice. The lord therefore had no wardhip, if at the death of the ancellor the heir-male was of the full age of 21 , or the heir-female of 14 : yet if the was then under 14, and the lord once had her in ward, he might keep her fo till 16, by virtue of the ftatute of Weflmirfter, I. 3 Edw. I. c. 22. the two additional years being given by the legillature for no other reafon but merely to benefit the lord.

This wardihip, fo far as it related to land, though it was not nor could be part of the law of feuds, fo long as they were arbitrary, temporary, or for life only; yet when they became hereditary, and did confequently often defcend upon infants, who by reafon of their age could neither perform nor Alipulate for the fervices of the feud, does not feem upon feodal principles to have been unreafonable. For the wardhip of the land, or cultody of the feud, was retained by the lord, that he might out of the profits thereof provide a fit perfon to fupply the infant's fervices till he fhould be of age to perform them himfelf. And if we confider a feud in its original import, as a flipend, fee, or reward for actual fervice, it could not be thought hard that the lord fhould withhold the flipend fo long as the fervice was fufpended. Though undoubtedly to our Englifh anceftors, where fuch flipendary donation was a mere fuppofition or figment, it carried abundance of hardfhip ; and accordingly it was relieved by the charter of Henry I. which took this cuftody from the lord, and ordained that the cuftody, both of the land and the chilidren, fhould belong to the widow or next of kin. But this noble immunity did not continue mary years,

The wardhip of the body was a confequence of the wardflip of the land; for he who enjoyed the infant's eftate was the propereft perfon to educate and maintain him in his infancy: and alfo, in a political viers, the lord was moft concerned to give his tenant a fuitable education, in order to qualify him the better to perform thofe fervices which in his maturity he was bound to render.

When the male heir arrived at the age of 2I, or the heir-female at that of 16 , they might fue out their livery or ouferlemain; that is, the delivery of their lands.

Waddhip out of their guardian's hands. For this they were obliWirn. ged to pay a fine, namely, half-a-ytar's profits of the Warn. land; though this feems exprefily contrary to majna
chatsa. However, in confideration of their lands having been fo long in ward, they were exculed all reliefs, and the king's tenants alfo all primer feifins. In order to afcertain the profits that arofe to the crown by thefe fruits of tenure, and to grant the heir his livery, the itinerant júflices, or juftices in eyre, had it formerly in charge to make mquifition concerning them by a jury of the county, commoniy called an inquifitio pof morsem; which was inflituted to inquire (at the death of any man of fortune) the value of his eflate, the tenure by which it was holden, and who, and of what age, his heir was; thereby to afcertain the relief and value of the primer feifin, or the wardhip and livery accruing to the king thereupon. A manner of proceeding that came in procefs of time to be greatly abuied, and at length an intolerable grievance; it being one of the principal accufations againt Empfon and Dudley, the wicked engines of Henry VII, that by colour of falfe inquifitions they compelled many perfons to fue out livery from the crown, who by no means were tenants thereunto. And afierwards a court of wards and liveries was ere Atcd, for conducting the fame inquiries in a more folemn and legal manner.

When the heir thus came of full age, provided he held a knight's fee, he was to receive the order of knighthood, and was compellable to take it upon him, or elfe pay a fine to the king. For in thofe heroical times no perfon was qualificd for deeds of arms and chivalry who had not received this order, which was conferred with much preparation and folcmnity. We may plainly difoover the footteps of a fimilar cuffom in what Tacitus relates of the Germans, who, in order to qualify their.young men to bear arms, prefented them in a full affembly with a flield and lance; which ceremony is fuppofed to have been the original of the feodal knighthood. This prerogative, of compelling the vafTals to be knighted, or to pay a fine, was exprefly recognifed in parliament by the ftatute de militibus, I Ldw. II.; was exerted as an expedient for raifing money by many of our beft princes, particularly by Edw. VI. and Queen Elizabeth; but this was the occation of heavy murinurs when exerted by Charles I. : among whofe many misfortunes it was, that neither himfelf nor his people feemed able to diflinguifh between the arbitrary Atretch and the legal exertion of prerogative. However, among the other conceffions made by that unhappy prince before the fatal recourfe to arms, he agreed to diveft himfelf of this undoubted flower of the crown ; and it was accordingly abolifhed by fatute 16 Car. I. c. 20.

IWARE, a town of Hertfordhire, with a marhet on Tuefdays, and a fair on the laft Tuerday in April, and 'Tuclday before St Matthew's day (Sep. 2I,) for horles and other cattle. It is a large, well frequented, and well inhabited thoroughfare town, feated on the river Lea, 21 miles north of London. It carries on a great trade in malt and corn, which they are continually fending in large quantities to London. E. Long. O. 3 . N. Lat. 5 I. 50 .

WARN, in Law, is to fummon a perfon to appear in a court of juftice.

WARNING of TENANTS, in Scots Lew. ... Sec Law, No clxvii. 16.

WARP, in the manufaclures, a name for the threads, whether of filk, wool, linen, hemp, \&c. that are extended lengthwife on the weaver's loom; and acrofs which the workman, by means of his shuttle pafo fes the threads of the woof, to furm a cloth, ribband, fultian, or the like.

WARP, a fmall rope employed occafionally to remove a hhip from one place to another, in a port, road, or river. And hence,

To WARP, is to change the fituation of a flip, by pulling her from one part of a harbour, \& c. to fome other, by means of warps, which are attached to buoys; to anchors funk in the bottom; or to certain flations upon the floore, as polls, rinds, trees, \&c. The flip is accordingly diawn forwards to thofe ftations, either by pulling on the warps by hand, or by the application of fome purchafe, as a tackle, windlafs, or capftern, upon ber deck.

When this operation is performed by the fhip's lefler anchors, thefe nachines, together with their warps, are carried out in the boats aliernately towards the place where the thip is endeavouring to arrive: fo that when fhe is drawn up clofe to one anchor, the other is carried out to a competent diftance before ber, ard being funk, ferves to fix the other warp, by which the is farther advanced.

Warping is gencrally ufed when the fails are unbent, or when they cannot be fuccersfully employed, which may either arife from the unfavourable fate of the wind, the oppofition of the tide, or the narrow limits of the channel.
warrandice, in Scots Law. See Law, Ne clxiv. 11.

WARRANT, is a power and charge to a confable or other officer to apprehend a perfon accufed of any crime. It may_be iffued in extraordinary cafes by the privy council, or fecretaries of flate; but mof commonly it is ifrued by jultices of the peace. This they may do in any cafes where they have a jurididition over the offence, in order to compel the perfon accufed to appear before them; for it would be abfurd to give them power to examine an offender, unlefs they had alfo power to compel him to attend and fubmit to fuch examination. And this extends to all treafons, felonies, and breaches of the peace; and alfo to all fuch offences as Blarifg they have power to punifit by ftatu'e. Before the grant-vol. it. p. ing of the warrant, it is fitting to examine upon oath the 290 . party requiring it, as well to afcertain that there is a felony or other crime actually committed, without which no warrant fhould be granted; as alfo to prove the caule and probability of fufpecting the party againf whom the warrant is prayed.

This warrant ought to be under the hand and feal of the juftice; flould fet forth the time and place of making, and the caufe for which it is made; and flould he direated to the conftable, or, other peace officer, or it may be to any private perfon by name. A general warrant to apprehend all perfons fufpecied, without naming or particularly defcribing any perfon in fpecial, is illegal and void for its uncertainty; for it is the duty of the magifirate, and ought not to be left to the ufficer, to judge of the ground of firipicion. Alfo a warrant to ap-

\footnotetext{

}
prehend all perfons guilty of fuch a crime, is no legal warrant ; for the point upon which its authority rells, is a fact to be deceided on a fubfequent trial ; namely, whetner the perfon apprchended thereupon be guity or not guilty. When a warrant is reccived by the officer, he is bound to execute it, fo far as the jurifdittion of the magiftrate and himfolf extends. A warrant from any of the junices of the court of king's bench extends over all the kingdom, and is tefted or dated England: but a warrant of a juffice of the peace in one county, muf be backed, that is, figned, by a juftice of another county, before it can be executed there. And a warrant for apprehonding an Englifh or a Scotch offender, may be indorfed in the oppofite kingdom, and the offender carried back to that part of the winited kingdom in wh:: b the offence was committed.

Warranty, Warrantia, in Lare, a promie, or covenant, by deed, made by the bargainer for himfelf and his heirs, to warrant and fecure the bargainee and his heirs, againft all men, for enjoying the thing agreed on or granted between thern.

W ArRen, Sir Peter, an admiral, difinguihed by his virtue, learning, and undaunted courage, was defeended from an ancient family in Ircland, and received a fuitable education to qualify him for a command in the royal navy, in which he ferved for feveral years with great reputation; but the tranfaction which placed his great abilities in their full light, was the taking of Lauifbourg in the year \(\mathbf{1 7 4 5}\), when he was appointed commodore of the Britinh iquadion fent on that fervice. \(H=\) joined the fleet of tranfports from Bofton in Canfo buy on the 25th of April, having under his command the Superb of 60, and the Launcefton and Eltham of 40 guns; he was afterwards joined by feveral other men of war fent from England, and tuok poffelion of Louifburg on the 17 th of June. The French, exalperated at this lofs, were conftantly on the watch to retake it ; and in 1747 fitted out a large fleet for that purpofe, and at the fame time another fquadron to profecute their fuccefs in the Eaft Indies. Thefe fruadrons failed at the fame time; but the views of the French were reindered abortive by the gallant admiral Anfon and Sir Peter Warren, who had been created rear-admiral, who with a large Beet of fhips fell in with the French, defeated the whole fleet, and took the greatef part of the men of war. This was the laff fervice Sir Peter rendered to his country as a communder in the Britith fleet; for a peace being concluded in the fucceeding year, the fleet was laid up in the feveral harbours.

He was now chofen one of the reprefentatives in parliament for Weftminfer; and in the midft of his popularity he paid a vifit to Ireland, his native country, where he died of an inflammatory fever in 1752 , fincerely lamented by all ranks of people; and an elegant monument of white marble was erected to his memory in Weftminfter abbey.

Warren, is a franclife or place privileged by pre. fcription or grant from the king, for the keeping of beafts and fowls of the warren ; which are hares and conevs, partridges, pheafants, and fome add quails, woodcocks, and water-fowl, \&c. Thefe being ferce naturar, every one had a natural right to kill as he could : but upon the introduction of the foreft laws at the Norman conquef, thefe ánimals being looked upon as royal grime, and the fole property of our favage monarchs, this fran-
chife of free-warren was invented to protect thiem, by giving the grantee a lole and exclufive power of killing fuch game, fo far as his warren extended, on condition of his preventing other perfons. A man therefore that has the franchife of warren, is in reality no more than a royal game-keeper : but no man, not even a lord of a manor, could by common law julify fporting on another's loil, or even on his own, wilefs lie had the lizerty of free-warren. This franchife is almolt fallen into difregard fince the new flatutes for preierving the game; the name being now chiefly prcferved in grounds that are fet apart for breeding hares and rabtits. There are many inflances of keen loortfmen in ancient times, who have fold their ellates, and referved the free-wanen, or right of killing gane, to themfe!ves: by which means it comes to pafs that a man and his heirs have fometimes frec-warren over another's ground.

A warren may lie open; and there is no neceflity of inciofing it as there is of a park. If any perfon offend in a free-warren, he is puniliable by the common law, and by thatute 21 Edw. III. And if any one enter wrongfully into any warren, and chafe, take, or kill, any coneys without the confent of the owner, he fhall forfeit teeble damages, and liffier three months imprifunment, \&c. by 22 and 23 Car. II. c. 25. When concys are ont the fuil of the party, he hath a property in them by reafon of the poffeflion, and ation lies lor killing them; but if they run out of the warren and eat up a neighbour's corn, the owner of the land may kill there, and no action will lie.

WARSAW, a large city of Poland, the capital of that country, and of the province of Mafovia. It is built. partly in a plain, and partly on a gentle afcent rifing from the banks of the Viltula, which is about as broad as the Thames at Weftminfter, but very fhallow in fummer. This city and its fuburbs occupy a vaft extent of ground, and are fuppoied to contain 70,000 inhabitants, among whom is a great number of foreigners. The whole has a melancholy appearance, exhibiting the flrong contrait of wealth and pnverty, luxury and diltrefs, which pervades every part of this unhappy country. The flreets. are fpacious, but ill paved; the churches and public buildings are large and magnificent; the palaces of the nobility are numerous and fplendid; but the greateft part of the houfes, particularly in the fuburbs, are mean. and ill conftrusted wooden hovels.- Warfiw is 160 miles fouth-eafl by fouth of Dintzic, 33 north north-eaft of Cracow, and 300 north ealt by north of Vienna. E. Long. 21. 6. N. Lo?. 50.14.

IVART. See Surgery Index.
WARWICK, the capital of Warwirknire in England, and from which this county derives its name. It is very ancient, and fuppofed by Camden to be the place called by the Romans Prefifium, where the Dalmatian. horfe were pofted. It flands on a rock of f:eeftone, of which all the public edifices in the town are built. At the Norman invalion it was a confiderable place; and had many burgefles, of whom 12 were obliged by their tenure to accompany the king in his wars. It is fup. plied with water brought in pipes from furings half a mile from the town, belides what it derives from the wells within it made in the rock: and it is eafily kept clean, by being fituated upon a declivity. Four ftreets, from the four cardinal points of the compafs, nese in the centre of the town. The principal public buildings are

Warren II Wa.yak,

\section*{W A R}

Wazwick- St Mary's, a very fately edifice, an hofpital, a townhaire. houfe of freeftone, three charity fchools, and a noble
bridge over the Avon. It has had ieveral charters; but is governed at prefent by a mayor, 12 brethren, 24 burgelles, \&zc. It contains 5775 inhabitants; and gives title of earl to the family of the Grevilles. W. Long. 1. 36. N. Lat. 52. 20.

WARWICKSHIRE, a county of England, 47 miles in length, by 30 in breadth. It is bounded at its northern extremity by a point of Derbyifire ; on the norih-weft by Staffordhire; on the north-eaft by Leicefterflire; on the eaft by Northamptonfhire; on the fouth-weft by Gloucefterhire, and on the fouth-eaft by Oxfordhire. It is fituated partly in the diocefe of Lichfield and Coventry, and partly in that of Worcefter; it contains four hundreds, and one liberty, one city, 12 market towns, 158 parifhes; fends fix members to parliament, and the population is computed at 208,190. The air is mild, pleafant, and healthy. The river Avon divides the north part of it, or the WoodIands, from the fouth, called the Feldon; and the foil of both is rich and fertile. Its productions are corn, malt, wood, wool, cheefe, coal, iron, and limeftonc. The chief rivers of this county are the Avon, Tame, and Arrow. Warwick is the capital; but Birmingham is far fuperior to it in refpect of trade and manufactures, and even to any other town in England.

Birmingham, in this county, of which the account given in the lorder of the alphabet is very dcficient, is one of the moft remarkable towns in England, or perhaps in Europe, for the extent, variety, elegance, and utility of its manufactures. This town was little diflinguifhed previous to the reign of Charles 1I. but fince that 'period it continued to increafe in extent and importance. In the year 1700, the number of ftreets in Birmingham was only 30 ; they are now nearly 250 . In the year 1779 there were only three houfes on a particular foot, which in 1791 contained 833 .

Birminglam owes its profperity and population to its manufaciures, which are in a great meafure the confequence of its vicinity to coal, aided by the firited and induftrious exertions of a few individuals. It has been flated, and no doubt with great truth, that its profperity is in no fmall degree indebted to its exemption from the reffrictions of borough and corporate laws. To give fome notion of the progrefs and extent of the manufactures of this place, it may be mentioned that the late Mr Taylor, who introduced gilt buttons, japanned, gilt, and painted fnuff-boxes, with various articles of manufacture in enamel, died in 1775, at the age of 64, having "amaffed a fortune of 200,000 . In painting fnuff-boxes at fo low a rate as one farthing each, one man could gain 3l. 10s. per week. The weekly produce of \(\mathrm{Mr}^{\text {'Taylor's manufacture of buttons amounted }}\) to 8001 . befide many other valuable and curious productions.

The manufactory of Meffrs Boulton and Watt, which for its extent, variety, and importance, flands unrivalled in Europe, has been already noticed under the word Sono. The new coinage of copper, which has been often defervedly admired, and the re-ftamped dollars, are the productions of the Soho manufactory. The firft coining mill was erected at Soho in 1783 . It is now fo much improved, that eight machines driven by the fleam-engine, are going on at the fame time. Each
of thofe machines Atrikes from 70 to 84 pieces of the fize of a guinea per minute, and hence the whole eight machines work off in one hour between 30,000 and 40,000 coins. The different proceffes of the machinery are, 3. Kolling the mafles of copper into fheets. 2. Rollo ing them through cylindrical fteel rollers. 3. Clipping the pieces of copper for the dye. 4. Shaking the coin in bags." 5. Striking bath fides of the coin, and then mill. ing it ; after which it is difplaced, and another is introduced, to be fubjected to the fame operation. But the moft extraordinary contrivance of this ingenious machinery is, that a precife account of every coin which paffes through it is regularly kept, fo that it is impoffible to practife fraud.

Befide the branches of induftry already mentioned, there are manufactories of guns, bayonets, and fwords, of fporting guns, of whips, of japan ware, of numerous works in brafs and fteel, both for ornament and ufe, and at one time of leather to a confiderable extent.

Birmingham contains a mufeum of natural and artificial curiofities, a handfome theatre, rebuilt fince 1791, feveral churches belonging to the eftablifhment, various diffenting meeting houfes, and a number of charitable eftablifhments. In the neighbourbood of Birmingham there are three extenfive breweries; and by means of canals this place has the advantage of eafy communication with almof every part of the kingdom.

WASH, among diffillers, the fermentable liquor ufed by malt diftillers. See Brewery.

WASHING, in Painting, is when a defign, drawn with a pen or crayon, has fome one colour laid over it with a pencil, as Indian ink, biftre, or the like, to make it appear the more natural, by adding the fhadow of prominences, apertures, \&c. and by imitating the particular matters whereof the thing is fuppofed to confift.

Thus a pale red is employed to imitate brick and tile; a pale Indian blue, to imitate water and flate; green, for trees and meadows; faffron or French berries, for gold or brafs; and feveral colours for marbles.

W ASHING of Ores, the purifying an ore of any metal, by means of water, from earths and fones, which would otherwife render it difficult of fufion.

WASHINGTON, a city of North America, and now the metropolis of the United States. It is feated at the junction of the rivers Potomac and the Eaftern Branch, extending about four miles up each, in. cluding a tract of territory fcarcely to be exceeded, in point of convenience, falubrity, and beauty, by any in the world. This territory, which is called Columbia, lies partly in the ftate of Virginia, and partly in that of Maryland, and was ceded by thofe two flates to the United States of America, and by them eftablifhed to be the feat of government after the year 1800 . It is divided into fquares or grand divifions, by ftreets running due north and fouth, and eaft and weff, which form the ground-work of the plan. However, from the Ca pitol, the prefident's houfe, and fome of the important areas in the city, run diagonal Areets, from one material object to another, which not only produce a variety of charming profpects, but remove the infipid famenefs which renders fome other great cities unpleafing. The grest leading freets are all \(\mathbf{3} 60\) feet wide, including a paveinent of 10 feet, and a gravel walk of 30 feet planted with trees on each fide, which will leave 80 feet of paved ftreet for carriages. The reft of the ftreets are in

7alling- general 110 feet wide, with a few eviy go feef, except North, South, and Eat Capitol Streets, which are 160 feet. The diagonal firects are named after the refpective flates compofing the Unior, while thofe runniug north and foutha are, from the Caritol eaflward, mamed Jiaf Fird Strect, Eial/ Second Sert, \&zc. and thofe wert of it are in the fame manner cal Wof Firf Sireet, Wift Second Strece, \&ec. Thoic running calt and weit are froos the Capitol northward named Nuth A Street, North B Street, \&ec. and thofe fouth of it are called South A Sereet, Sorth B Street, \&\&c. The fquares or divifions of the city amount to 1150 . The rectangular fquares generally contain from three to fis acres, and are divided into lots of froan 40 to So feet in front, and their depth from about 110 to 300 feet, accorditig to the fize of the fquare. The irregular divifions produced by the diagonal itreets are fome of them fraall, but generally in valuable fituations. Their acute points are all to be cut off at 40 fcet, fo that no houfe in the city will have an acute coruer. All the houfes mult be of brick or flone. The area for the Capitol (or houfe for the legiflitive bodies) is fituated upon the moft beautiful eminence in the city, about a mile from the Ealtern Brarth, and not much more fro:n the Putomac, commanding a full vicw of every part of the city, as well as a confiderable cxtent of the country around. The prefident's houle will fand upon a rifing ground, not far from the banks of the Poiomac, puffefling a delightful water profpect, with a commanding view of the Capitol, and fome other material parts of the city.

The city being fituated upon the great polt road, exadly equidifant from the northern and fouthern extremities of the Union, and nearly fo from the Atlantic ocean to the river Ohio, upon the beft navigation, and in the mida of the richef commercial territory in America, commanding the moft exterfive internal refources, is by far the moft cligible fituation for the refidence of congrefi; and it is now prefling forward, by the publicfpirited enterprife, not only of tha people of the United Siates, but alfo of foreigners.
W asiringron, George, the celebrated comnander of ihe Amcrican army, and the fritt prelident of the United States, after their feparation from the mother-country, was born in the ycar 1732, in the parifl of Wafhington in Virginia. He was defcended foom an ancient family in Chethire, of which a branch was eltablifled in Virginia abont the middle of the 17 th century. Litthe is known conceming his education, or the early years of his life. Before he was 20 ycars of age, he was anpuinted a major in the colonial militia, and had then an opportunity of difplaying thofe military and political talents which have fince rendered his name fo famous througheut the world. In the difputes which arofe between the French and Englih officers, about Fettling the limits of Canada and Louifiana, Major Waflington was employed by the governor of Virginia as a negociator, and he ficceeded in preventing a threatened invafion of the Englifh frontiers hy the French and their Indian allics; but, in the following year, when hoftilities feemed inevitable, he, was, appointed liemtenant-colonel, and fon after to the command of a regiment raifed by the colony for its own defence. In 5755, Colonel Wafhington ferved as a velunteer in the unfortunate exoedition of Genera! Braddock, and in that expedition, which was attended with great difficulty,

Vol. XX, Patt II.
he exhibited fo much calumefs and intrepidity, that the Wahingutmolt confidence was requfed in his talents, and perfeet obedience paid to his cormmands by the whole army. After having boen employed in a d.fferent and more fuccelisful cripedition to the river O.in, the tate of his health required him, about the ye ir 1758, to re-
 years, during which period he marrical Mis Cuttis, a Virginian lady, of amiable claracter and refpectable connections. it would appear that be refided clicit? ai his be:muiful feat of Mount Yerno:2, and was occui idd in the cultivation of his chatr.

When the dififledion of the Amerieans to the B3:itifh government had become pret y general, and had at latt fipread to the colony of Virginia, Culorel Wahington was appointed a delegate from that fatc to the co: grefs which met at Philadelphia on the 26th Uetober 177.4, and foon after he was appointed to the command of the Amelican army, which had allembled in the provinces of New Englamd. The conduct of Wahington during the whole of the war, as well as during the period that he prefided in the government of the United States, has been fo fully detailed in another part of this work, that it would be unneceflary repetition, crota to give a general outline of it in this place. Sec Alme. RICA.

Wahlington refigned the prefidency in : 796 , aftee having publifhed a farewell addrcfs to his countrymen. This addrefs was remarkably diftinguiked for the finsplicity and ingenuoufnefs, moderation and fobricty, the good fenfe, prudence and honcity, as wcll as fincere affcation for his country and for mankind, which the anthor of it had always exhibited; it leemed to be a perfect piture of his whole life. Ftom the time of his refignation till the month of July \({ }^{1} 798\), l.c lived in retirement at his feat of Mount Vernon. At this period, when the unprincipled actors in the Frencls revolution were carry.. ing on their wicked machinations in every part of the norld to which their influence extended, the United States refolved to arm by land and fea is their own defence. General Wafhington was called from his retirement, and the command of the army was betlowed upon him. This he accepted, becaufe he coulidered, as he himfelf exprefied it, "every thing we loold doar and facred was ferioully threatened, although he had llattered himielf that he had quitted for ever the boundicls field of public action, inceliant trouole, and high refpenfibility, in which he hàd long acted fo conficuove a part.:" In this fituation he continued during the remaining thort period of his life. On Thurfday the 12 th of December 1799, he was feized with an inflammation in the throat, and was cartied off on Saturday the ifth of the fanme month, in the 68th year of his age. In his dying moments he difplayed the fame calmnefs, fmplicity, and regularity, which had uniformly marked his conduct through life. He faw the approaches of death without fear; and he met them without parade. Even the perfectly well ordered fate of the minutelt particulars of his private bulinefs bear the ftamp of that conftant anthority of prudence and practical reafon over his actions which was always the moft prominent featurc of his character.

Wishisg on is the name of many counties, towns, and villages in the American fates; a circumflance which affords a ftr:ling proof in what degree of efteem

\section*{W A T [ 642 ] W A T}

Waip, Watch.
and veneration the name from which they are derived was held by the inhabitants of the new world.
WASP. Sec Vespa, Entomology Index.
WATCH, in the art of war, a number of men polted at any palfage, or a compariy of the guards who go on the patrole.
\(W_{\text {atch, }}\) in the navy, the fpace of time wherein one divition of a fhip's crew remains upon deck, to perform the neceflary fervices, whilit the reft are relieved from duty, cither when the veflel is under fail or at anchor.

The length of the fea-watch is not equal in the Chipping of different nations. It is al:ways kept four hours by our B-itifh feanen, if we except the dog-watch, between four and eight in the evening, that contains two reliefs, each of which are only two hours on deck. The intent of this is to change the period of the night-watch every 24 hours; fo that the party watching from eight till 12 in one night, fhall watch from midnight till iour in the morning on the fucceeding one. In France the duration of the watch is extremely different, being in fome places fix hours, and in others leven or eight; and in Turkey and Barbary it is ufually five or fix hours.

A thip's company is ufually claffed into two parties; one of which is callcd the flarboart and the other the larboard watch. It is, however, occafionally feparated into three divifions, as in a road or in particular voyages.

In a mip of war the watch is generally comananded by a lieutenant, and in merchant-fhips by one of the mates; fo that if there are four mates in the latter, there are two in each watcla; the firlt and third being in the larboard, and the fecond and fourth in the flarboard watch: but in the navy, the officers who command the watch ufually divide themfelves into three parties, in order to lighten their duty.

Watch, is alfo uled for a finall portable movement, or machine, for the meafuring of time; having its motion regalated by a fpiral fpring.

Waiches, frictly taken, are all fuch movements as how the parts of time; as clocks are fuch as publifh it, by ftriking on a bell, \&cc. But commonly the name watch is appropriated to fuch as are carried in the pocket; and clock to the large movements, whether they flrike the hour or not. See Clock.

The invention of fpring or pocket-watches belongs to the prefent age. It is true, we find mention made of a watch prefented to Charles V . in the hiftory of that prince: but this, in all probability, was no more than a kind of clock to be fet on a table, fome refemblance \(w^{h}\) hereof we have fill remaining in the ancient pieces made before the year 1670. There was alfo a ftory of a watch having been difcovered in Scotland belonging to King Robert Bruce; but this we believe has turned out altogether apocryphal. The glory of this very ufeful invention lies between Dr Hooke and M. Huyghens; but to which of them it properly belonge, has been greatly difputed; the Englifh afcribing it to the former, and the French, Dutch, \&ec. 10 the latter. Mr Derham, in his Artificial Clockmaker, fays roundly, that Dr Hooke was the inventor; and adds, that he contrived various ways of regulation. One way was with a loadflone: Ancther wilh a tender ftraight fpring, one end whereof played backwards and forwards with the balance; fo that the balance was to the fring as the bob to a pendulum, and the fpring as the rod thercof: A third method was with two balarices, of which there were divers
forts; fome haviug a fpiral fpring to the balance for a regulator, and others without. But the way that prevailed, and which continues in mode, was with one balance, and one foring running round the upper part of the verge thereof: Though this has a diladvantage, which thofe with two fprings, \&c. were free from ; in that a fudden jerk, or consufed fhake, will alter its vi. brations, and put it in an unulual hurry.

The time of thefe inventions was about the year 1658 ; as appears, among other evidences, from ath infcription on one of the double balance watches frefented to King Charles II. viz. Rob. Hooke ingen. 16;8. 'I'. Tompion fecit, 1675. The invention prefently got into reputation, both at home and abroad ; and two of them were fent for by the dauphin of France. Soon afte: this, M. Huygen's watch with a fpiral fpring got abroad, and made a great noife in England, as if the longitude could be found by it. It is certain, however, that his invention was later than the year 1673, when his bools de Horol. Ofrillat, was publifhed; wherein he has not one word of this, though he has of feveral other contrivances in the fame way.

One of thefe the lord Brouncker fent for out of France, where M. Huygens had got a patent for them. This watch agreed with Dr Hooke's in the application of the fpring to the balance; only M. Huygens's liad a longer fpiral fpring, and the pulles and beats were much flower. The balance, inftead of turning quite round, as Dr Hooke's, turns feveral rounds every vibration.

Mr Derham fuggells, that he has reafon to doubt M. Huygens's fancy firit was fet to work by fome intelligence he might have of Dr Hooke's invention from Mr Oldenburgh, or fome other of his correfpondents in Eng. land; and this, notwithflanding Mr Oldenburgh's attempt to vindicate himefelf in the Philofophical Tranfactions, appears to be the truth. Huygens invented divers other kinds of watches, fome of them without any ftring or chain at all; which he called, particularly, pendulum watches.

Striking WATCHEs are fuch as, befides the proper watch-part for meafuring of time, have a clock-part for friking the hours, \&c.

Rcpeating Watches, are fuch as by pulling a ftring, \&c. repeat the hour, quarter, or minute, at any time of the day or night.-This repetition was the invention of Mr Barlow, and firft put in practice by him in larger movements or clocks about the year 1676 . The contrivance immediately fet the other artifts to work, who foon contrived divers ways of effecting the fame. But its application to pocket-watches was not known before King James II.'s reign ; when the ingenious inventor above mentioned, having directed Mr Thompfon to make a repeating watch, was foliciting a patent for the fame. The talk of a patent engaged Mr Quare to refume the thoughts of a like contrivance, which he had had in view fome years befote: he now effefted it; and being preffed to endeavour to prevent Mr Barlow's patent, a watch of each kind was produced before the king and council; upois trial of which, the preference was given to Mr Quare's. The difference betwcen them was, that Barlow's was made to rejeat by pulhing in two pieces on each fide the watch-box; one of which repeated the hour, and the other the quarter : whereas Quare's was made to repeat by a pin that fluck out near the pendant, which being thruf in (as

\section*{W A TI [643] W \(] \quad{ }^{T}\)}
now it is done by thrußing in the pendant itfelf), repeated both the hour and quarter with the fame thruf.

Of the Mechanifm of a Wrctr, properly fo called. Watches; as well as clocks, are compofed of wheels and pinions, and a regulator to direct the quicknefs or flownels; of thie wheels, and of a fpring which communicates motion to the whole machine. But the regulator and fpring of a watch are vaftly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we ate obliged to ufe a balance (fig. I.) to regulate the motion of a watch; and a fpring (fig. 2.) which ferves in place of a weight, to give motion to the wheels and balance.

The wheels of a watch, like thofe of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. reprefents the infide of a watch, after the plate (fig. 4.) is taken off. A is the barrel which contains the fring (fig. 2.) ; the chain is rolled about the barrel, with one end of it fived to the barrel A (fig. 5.), and the other to the fufee B.

When a watch is wound up, the chain whicl was upon the barrel winds about the fufee, and by this means the fpring is itretched; for the interior end of the fpring is fixed by a hook to the immoveable axis, about which the barrel revolves; the exterior end of the furing is fixed to the infide of the barrel, which turns upon an axis. It is therefore eafy to perceive how the fpring extends itfelf, and how itselufticity forces the barrel to turn round, and confequently obliges the chain which is upon the fufee to unfold and turn the fufee; the motion of the fufee is communicated to the wheel \(\mathbb{C}\) (fig. 5.) ; then, by means of the teeth, to the pinion \(c\), which carries the wheel D ; then to the pifton \(d\), which carries the whecl E; then to the pinion \(e\), which carries the wheel F ; then to the pinion \(f\), upon which is the balance-wheel \(G\), whofe pivot runs in the pieces A called the potarce, and B calledi a follower, which are fixed on the plate fig. 4. This plate, of which only a part is reprefented, is applied to that of fig. 3 . in fuch a manner that the pivots of the wheels enter into holes made in the plate fig. 3. Thus the impreffed force of the fpring is communicated to the wheels: and the pinion \(f\) being then ronnected to the wheel F, obliges it to turn (fig. 5.). This wheel acts upon the palettes of the verge, 1,2, (fig. 1.), the axis of which carries the balance HH , (fig. I.). The pivot \(I\), in the end of the verge, enters into the hole \(c\) in the potance \(A\) (fig. 4.). In this figure the palettes are reprefented; but the balance is on the other fide of the plate, as may be feen in fig. 6 . The pivot 3 of the balance enters into a hole of the cock BC (fig. 7.), a perfpective view of which is reprefented in fig. 8 . Thus the balance turns between the cocl: and the potance \(c\) (fig. 4.), as in a kind of cage. The action of the balance-wheel upon the palettes 1,2 (fig. I.), is the fame with what we have defcribed with regard to the fame wheel in the clock; i. \(c\). in a watch, the balance-rheel obliges the balance to vibrate backwards and forwards like a pendulum. At each ribra. tion of the balance a palette allows a tooth of the ba-lance-wheel to efcape; fo that the quicknefs of the motion of the wheels is entirely determined by the quicknefs of the vibrations of the balance; and thefe vibrations of the balance and motion of the wheels are produred by the action of the fpring.
- But the quickncis or Mownefs of the vibrations of the
balance depend not folely upon the action of the great Waitil. fping, but chiefly upon the aetion of the fpring \(a, b, c\), called the fpiral fpring (fig. 9.), fituated under the ba-Fig. 9. lance \(H\), and reprefented in perfpective (fig. 6.). The cxterior end of the fpiral is fixed to the pin a, (fig. g.) 'This pin is applied near the plate in \(a\), (fig. 6.) ; the interior end of the fpiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itfelf, the plates remaining immoveable, the fpring will extend itfelf, and make the balance perform one revolu. tion. Now, after the fpiral is thus extended, if the balance be left to itfelf, the elallicity of the fpiral will bring back the balance, and in this manner the aiternate vibrations of the balance ate produced.

In fig. 5 . all the wheels above defcribed are reprefented in fuch a manner, that you may eafly perceive at firft light how the motion is communicated from the barrel to the balance.

In fig. 10, are reprefented the wheels under the dial. Fig. ino plate by which the hands are moved. The pinion \(a\) is adjufted to the force of the prolonged pivot of the wheel D (fig. 5), and is called a connog pinion. This wheel revolves in an hour. The end of the axis of the pinion \(a\), upon which the minute-hand is fixed, is fquare: the pinion (fig. 10.) is indented into the wheel \(b\), which is
 a barrel, into the cavity of which the pinion a enters, and upon which it turns freely. This wheel revolves in 12 hours, and carries along with it the hour-hand. For a full account of the principles upon which watches and all time-keepers are conftructed, we muft refer our readers to a fhort treatilo, entitled Thoughts on the Mears of improving Watches, by Thomas Mudge.

W ATCII-Glafes, in a hip, are glaffes employed to meafure the period of the watch, or to divide it into any number of equal parts, as hours, half-hours, \&c. fo that the feveral dations therein may be regularly kept and relieved, as at the helm, pump, look-out, \& \(c\).

WATCH-Horé. There is one part of the movements of clocks and watches of which we have yct given no particelar account. This is the method of applying the maintaining power of the wheels to the regulator of the motions, fo as not to injure its power of regulation. This part of the conftruction is called Scaprment, and falls to be defcribed under the prefent article, to which we have referred from Scapembist.

The motions of a clock or watch are regulated by a Objects of pendulum or balance, without which oheck the wheelsfapements. impelled by the weight in the clock, or fpring in the watch, would run round with a rapidly accelerating motion, till this fhould be rendered uniform by friction, and the refiftarice of the air. If, however, a pendulum or balance be put in the way of this motion, in fuch a manner that only one tooth of a wheel can pafs, the revolution of the wheels will depend on the vibration of the pendulum or balance.

We camnot here enter on an hiforical account of the improvements that have been made on the regulating powers of clocks ard watches, nor can we detail the principles on which their action depends. It will be fufficient here to notice the mof fimple conftruction of fcapements, and then to defcribe two or three of the moft improved conftuctions that have been applied to time kcepets.

We know that the motion of a pendulum or balance

Watch. is alternate, while the preffure of the wheels is conftantly exerted in the fame direction. Hence it is evident that fome means mult be employed to acconmodate thefe different motions to each other. Now, when a sooth of the wheel has given the pendulum or balance a motion in one direction, it mufl quit it, that the pendulum or balance may receive an impulfion in the oppofite ciirection. This efooping of the tooth has given rife to the term frapement.
Bett urdi- The ordinary feapement is extremely fimple, and nary fcape- may be thus illuifrated. Let \(x y\) fig. 12 Plate DLXXI. clocks.
Fig. 12. reprefent a horizontal axis, to which the pendulum \(p\) is attached by a flender rod. This axis has two leaves \(c\) and \(d\), one near each end, and not in the fame plane, but fo that when the pendulum hangs perpendicularly at reit, \(c\) fpreads a few degrees to the right, and \(d\) as much to the left. Thefe are called the pallets. Let a \(f h\) reprefent a wheel, turning on a perpendicular axis \(f o\) in the order \(a f e b\). The tecth of this wheel are in the form of thofe of a farr, leaning forward in the direction of the rim's motion. This wheel is ufually called the crown-wheel, or in watches the balance-wheei. See Clocts and Watch. It generally contains an odd number of teeth. In the figure the pendulum is reprefented at the extremity of its excurfion towards the right, the tooth \(a\) having juft efcaned from the pallet \(c\), and \(b\) having juft dropt on \(d\). Now it is evident that while the pendulum is moving to the left, in the arch \(\rho g\), the tooth \(b\) ftill preffes on the pallet \(d\), and thus accelerates the fendulum, both in its defeent along \(力 h\), and its afcent up \(h g\), and that owhen \(d\), by turning round the axis \(x y\), raifes its point above the plane of the wheel, the tooth \(b\) efcapes from it, and \(i\) drops on \(c\), now nearly perpendicular. Thus \(c\) is preffed to the right, and the motion of the pendulum along \(g p\), is accelerated. Again, while the pendulum langs perpendicularly in the line \(x h\), the tooth \(b\), by preffing on \(d\), will force the pendulum to the left, in proportion to its lightnefs, and if it be not too heary, will force it fo far from the perpendicular, that \(b\) will efcape, and \(i\) will catch on \(c\), and force the pendulum back to \(p\), when the fame motion will be repeated. This effect will be more remarkable, if the rod of the pendulum be continued through \(a y\), and have a ball \(q\) on the other end, to balance \(p\). When \(b\) efcapes from \(d\), the balls are moving with a certain velocity and momentum, and in this condition the balance is checked when \(i\) catches on \(c\). It is not, however, inflantly flopped, but continues to move a little to the left, and \(i\) is forced a litle backward by the pallet \(c\). It cannot make its efcape over the top of the tooth \(i\), as all the momentum of the balance was generated by the force of \(b\), and \(i\) is of equal power. Befides, when \(i\) catches on \(c\), and the motion of \(c\) to the left continues, the lower point of \(c\) is applied to the face of \(i\), whicla now ads on the balance by a long lever, foon flops its motion in that direetion, and continuing to prefs on \(c\), urges the balance in the oppofite direction. It is eafy to fec that the motion of the whecl here mult be hobbling and unequal, which has given to this feapement the name of the recoiling fcapement.
Vibrations In confidering the utility of the following imprnved of pendu- feapement for clocks, we muft keep in mind the follums are ifo- lowing propofition, which, after the above illufration, itronots.
fearcely requires any direct proof. It is, that the natutal vitrations of a pendulum are ifochronous, or are per-
formed in equal times. The great object of the feapement Watch. is to preferve this ifochronous motion of the pendulum.

As the defect of the recoiling fcapement was long apparent, feveral ingenious artifts attempted to fubfitute Cummin in its place a fcapement that fhould produce a more re- fcapeme: gular and uriform motion. Of thefe, the fcapement for clocl. contrived by Mr Cumming appears to be one of the Tig. Is. moft ingenious in its conftruction, and moft perfect in its operation. The following conffruction is fimilar to that of Mr Cumming but rendered rather lefs complex for the purpofe of flortening the defription.

Let A B C, fig. 13 . reprefent a portion of the fwing wheel, of which O is the centre, and A one of the teeth; Z is the contre of the crutch, pallets, and pendulum. The crutch is reprefented of the form of the letter \(A\), baving in the circular crofs piece a dit \(i k\), alfo. circular, Z being the centre. The arm Z F forms the firft detent, and the tooth A is reprelented as locked on it at F . D is the firt pallet on the end of the arm \(\mathrm{Z} d\) moveable round the fame centre with the detents, bus independent of them. The arm \(d e\) to which the pallet D is attached, lies wholly behind the arm Z F of the detent, being fixed to a round piece of brafs ef \(f\), having pivots turning concentric with the axis of the pendulum. To the fame piece of brafs is fixed the horizontal arm \(c \mathrm{H}\), carrying at its extremity the ball H , of fuch fize, that the action of the tooth \(A\) on the pallet \(D\) is juft able to raife it up to the pofition here drawn. Z. \(\mathrm{P} p\) reprefents the fork, or pendulum rod, behind both detent and pallet. A pin \(p\) projects forward, coming through the flit \(i k\), without touching either margin of it. Attached to the for! is the arm \(m n\), of fuch length that, when the pendulum rod is perpendicular, the angular diftance of \(n q\) from the rode \(e q\) H juft cqual to the angulardiffance of the left fide of the pin \(p\) from the left end \(i\) of the flit \(i k\).

Now, the natural pofition of the pallet \(D\) is at \(\delta\), seprefented by the dotted lines, refling on the back of the detent \(F\). It is naturally brought into this pofition by its own weight, and fill more by the weight of the ball H . The pallet D , being fet on the forefide of the arm at Z , comes into the fame plane with the detent F and the frwing-wheel, though here reprefented in a different pufition. The tooth \(C\) of the wheel is fuppofed to have efcaped from the fecond pallet, on which the tooth A immediately feizes the pallet I, fituated at \(\boldsymbol{\delta}\), forces it out, and then reft on the detent \(T\), the pallet \(D\) leaning on the tip of the tooth. After the efcape of C, the pendulum, moving down the arch of femivibration, is reprefented as having attained the vertical pofition. Proceeding fill to the left, the fin \(p\) reaches the extremity \(i\) of the nit \(i k\); and, at the fame infant, the arm \(z\) touches the rod \(e \mathrm{H}\) in \(q\). The pendulum proceeding a hairsbreadth further, withdraws the detent \(F\) from the tooth, which now even pufles off the detent, by acting on the inclining face of it. The wheel being now unlooked, the tooth following C on the other fide afts on its pallet, puhthes it off, and refls on its detent, which has been rapidly brought into a proper pofition by the action of A on the inclining face of F . Py a fimilar action of \(C\) on its detent at the moment of efcape, \(F\) was brought into a pofition proper for the wheels beirg locked by the tooth A. As the pendulum fill goes on, the ball H , and rallet connceacd with it, are carricd by the arm \(m n_{2}\) and before the pin \(f\) again reaches the

\section*{W A T [ 645 ] W A T}

Watcl. end of the fit, which had been fuddenly withdrawn by the action of A on F , the pendulum comes to reft. It now returns towards the right, loaded with the ball II on the left, and thas the motion lof during the latt vibration is refored. When the pin \(p\), by its motion to the right, reaches the end \(k\) of \(i k\), the wheel on the right fide is unlocked, and at the fame inflant the weight \(H\) being raifed from the pendulum by the action of a tooth like B on the pallet \(D\), ceales to act.

In this fcapement, both pallets and detents are detached from the pendulun, except in the moment of unlocking the wheel, fo that, except during this fhort interval, the pendulum may be faid to be free during its whole vibration, and of courfe its motion mufl be more equable and undifturbed.
The confructing of a proper icapement for watches ior watches. requires peculiar delicacy, owing to the fimall fize of the machine, from which the error of \(\mathrm{T}^{\frac{z}{8} e}\) of an inch has as much effect as the error of a whole inch in a common clock. From the neceffary lightnefs of the balance, too, it is extremely difficult to accumulate a fufficient fuantity of regulating power. This can be done only by siving the balance a great velocity, which is effected hy concentrating as much as poffible of its weight in the rini, and making its vibrations very wide. The balance rim of a tolerable watch thould pafs through at leall ten inches in every fecond. Wibrations In confidering the moft proper fcapements for watches,
of a balance we may aflume the following principle, viz. that the of-arellichro- cillations of a balance urged by its fpring, and undillurb-
ed by extraneous föes, are ifochronous.

In ordinary pocket watches, the common recoiling fcapement of clocks is ttill employed, and anfwers the common purpofes of a watch tolerably well, fo that, if properly executed, a good ordinary watch will keep time within a minute in the day. Thefe watches, however, are fubject to great variation in their rate of going, from any change in the power of the wheels.

The folloring is confidered as the beft confruction of the common watch fcapement, and js reprefented by fig. 14. as it appears when looking Itraygh down on the end of the balance arbor. C marks the centre of the balance and verge; CA reprefents the upper pallet, or that next the balance, and CB the lower pallet; F and D are two teeth of the crown whel, moving from left 10 right; \(\mathrm{E}, \mathrm{G}\), a:e two teeth in the lower part, moving from right to left. The tooth 1) appeas as having jut efcaped from the point of \(C A\), and the tooilh \(E\) as laving juft conse in contact with CB. In practice, the feapement fould not be quite fo clufe, as by a mall inequality of the teeth, D inight be kept from efcaping at all. The following ase thought the beft proportions: The ditance between the front of the teeth (that is, of \(G, F, E, D)\), and the axis \(C\) of the balance, is \(\frac{1}{3}\) of FA , the diftance between the points of the teeth. 'The length \(\mathrm{CA}, \mathrm{CB}\) of the pallets is \(\frac{3}{5}\) of the fame degrees, and the front DH or FK of the teeth makes an angle of \(25^{\circ}\) with the axis of the crown wheel. The flopinis file of the tooth mult be of an epicycloidal form, fuited to the relative motion of the tooth and pallet.

It appears from thefe proportione, that by the adion of the tooth D, the pallet A can dirow o:nt till it reach \(\pi, \mathrm{I} 22^{\circ}\) from CL. the line of the crown-wheel axis. To this if we add BCA \(=95^{\circ}\), we fall have LCC \(a=120^{\circ}\). Again, B will throw out as far on the other fide.

Now, if from \(240^{\circ}\), the fum of the extent of vibration Watch. of both pallets, we take \(95^{\circ}\) the angle of the pallets, the remainder \(145^{\circ}\) will exprets the greatelt vibration which the balance can make, without ilriking the front of the tecth. firom feveral caules, however, this meafurc is too great, and \(120^{\circ}\) is reckoned a fufficient vibration in the beft ordinary feapement.

Of the improvements on the feapements of watches, onc of the moit important is that by Mr George Graham, which we thall proceed to defcribe. DE., fig. 15 . reprefents part of the rim of the balance whecl; \(A\) and C, two of its teeth with their faces \(b e\) formed into planes, inclined to the circumiference of the wheel in an angle of about \(15^{\circ}\), fo that the length \(b e\) of the face may be nearly quadruple of its height \(e \mathrm{~m}\). Let a circular arch ABC be defribed romen the centre of the wheel, and though the middle of the faces of the teeth. The axis of the balance will pafs through fame point \(B\) of this arch, and the mean circumference of the teeth may be faid to pafs through the centre of the verge. Ua this axis is fixcd a portion of a thin hollow cylinder bed, made of hard tempered iteel, or of fome hard and tough flone, fuch as ruby or lapphire. By this conftruction the portion of the cylinder occupies \(210^{\circ}\) of the circumference. The edge \(b\), to which the tooth approaches from without, is rounded off on both angles. The other edge \(d\) is formed into a plane, inclined to the radius about \(30^{\circ}\). Now, luppote the wheel prefled forward in the direction \(A C\), the point \(b\) of the tuoth, touching the sounded edge, will puh it outwards, tum:ing round the balunce in the ditection \(b c d\). The heel \(c\) of the tooth will efcape from this edge when it is in the pofition \(h\), and \(e\) is in the pofition \(f\). The point \(b\) of the tooth will now be at \(d\), but the edge of the cylinder will be at \(i\). The tooth therefore reils in the infide of the cylinder, while the balance continues its wibration a little way, in confequence of the inpulie it has received from the ation of the inclined plane. When this vibration is cuded, by the oppofition of the balance fpring, the balance will return, and the tooth now in the polition \(B\), rubbing on the infide of the cy linder, the balance comes back into its natural polition \(b c d_{\text {s }}\) with an accelerated motion by the action of its fringo, and would of iffelf vibrate as far as the other fide. It is, however, affited again by the tooth, which prefles on the edge \(d\), pulhes it aifle till it attain the pofition \(k\), when the toath entirely efcapes from the cylinder. At this inftant the other edge of the cylinder, having attainect the pofition \(/\), is in the way of the next tooth, which is now in the polition \(A\), while the balance contirues its vibration, the too\% refling and subbing on the outfide of the cylinder. Wien this vibration is finifl. ed, the balance, by the action of the fpring, refumes its firl motion, and as fuon as the bulance gets into its natural pofition, the tootl begins to aft on the cdge \(b\), pufhes it afide, efcapes from it, and drups as before in the inide of the cylinder. In this conftuction the arch of action or icapement is \(30^{\circ}=\) twice the angle wh ch the face of a tooth makes with the circumfereace.

It is necellary to explain how the cylinder is connceted with the verge, fo as to make fach a great :evolutio:a round the tooth of the wheel. The triangular tooth \(c h m\) is placed on the top of a littie pillar fixed into the end of the piece of brafs in D. forned in the rim of the whecl. Thas the plane of the wedge tooth is pa-
- Fratch. rallel to the plane of the wheel, but ot a fralli ditance above it. The verge is reprelented at fig. IG, and confiuts of a long hollow cylinder of hard feel, having a great portion of the metal cut out. If fpread out flat, this cylinder would affure the form of fig. I7; and if we conceive this flat piece rolled up till the edges GH , and \(\mathrm{G}^{\prime} \mathrm{H}^{\prime}\) unite, we thall have the exact form. The paat acted on by the point of the tooth is denoted by the doted line \(b d\), and the part \(\mathrm{D}, \mathrm{I}, \mathrm{F}, \mathrm{E}\), ferves to conrect the two eads.
This fcapement of Mr Graham is called a korizontal feapement, becaufe the balance is parallel to the other wheels.

Another fcapement of a fuperior conflruction was contrived by M. Lepaute of Paris, and is of fuch a fingular form as to render it extremely difficult to illuftrate it by a figure. The reprefentations at fig. 18 and 19 will, hovvever, give general readers fonie idea of its mode of action, and a fkilful artift will eafily fee how the feveral parts may be adapted to each other. ABC fig. I8. reprefents part of the rim of the balance wheel, having the pins \(1,2,3,4,5, \& \mathrm{c}\). projecting from its faces; the pins \(1,3,5\), being on the fide next the eye, and the pins 2 and 4 on the oppofite fide. \(D\) is the centre of the balance and verge, and the fmall circle round D reprefents its thickneff. But the verge in this place is crooked, that the rim of the wheel may not be intercepted by it. To it is attached a piece of hard tempered ftecl \(a b c d\), of which the part \(a b c\) is a concave arch of a circle, having D for its centre. It wants about \(30^{\circ}\) of a femicircle. The reft \(c d\) is alfo an arch of a circle, having the fame radius with the balance wheel. In the natural pofition of the balance, a line drawn from D , through the middle of the face \(c d\), is a tangent to the circumference of the wheel. But if the balance be turned round till the point \(d\) of the horn come to \(d^{\prime}\), and the pointc come to 2 , in the circumference in which the pins are placed, the pin prefling on the beginning of the horn or pallet, pufhes it afide, flides aloag it, and efcapes at \(d\), having generated a certain velocity in the balance. Let another pallet fimilar to that now defcribed be placed on the other fide of the wheel, but in a contrary pofition, with the acting face of the pallet turned a vay from the centre of the wheel. Let it be fo placed at \(E\), that the mornent the pin 1 on the upper ficle of the wheel efcapes from the pallet \(c d\), the pin 4 on the lower fite of the wheel falls on the end of the circular arch ef \(g\) of the other pallet. Now, if the pallets be connected by equal pulleys \(G\) and \(F\) on the axis of each, and a thread round both, fo that they thall turn one way ; the balance on the axis D , having received an impulfe from the pin \(x\), will continue its motion from A towards \(i\), and will carry the other pallet with a fimilar motion round the centre Efrom \(h\) to \(k\). The pin 4 will therefore reit in the concave arcl \(g f c\) as the pallet turns round. When the force of the balance is fpent, the pallet \(c d\) returns towards its firf pofition. The palict \(g h\) turns with it, and when the point of the firt has arrived at \(d\), the heginning \(g\) of the other araive at the pin 4; and, proceeding farther, this pin clcapes from the concave arch of 5 , and flides along the pallet \(g h\), pulling it afide, and of courfe urging the pallet round the centre F , and the balance on the axis 1) ronnd at the fame time, and in the famestireftion. The pin 4 -fcanes from the palket \(g h\), when \(/ 2\) arrives at 3 ; but while the
pin 4 is fiding along the yielding pallet \(g h\), the pin 3 is moving in the circumberence LDA; and the inftant that the pin 4 cfeapes from \(/ 2\) at 3 , the pin 3 arrives at 2 , where the beyinning \(c\) of the concave archi \(c b\) is read. to receive it. It therefore refts on this arch, whil
balance continues its motion, and this may Cuntmue till the point \(b\) of the arch comes to 2. The balance now ftops, its force being fpent, and then returns; and the pin 3 efcapes from the citcle at \(c\), lides along the yield. ing pallet \(c d\), and when it efcapes at 1 , another pin on the lower fide of the wheel arrives at 4 , and finds the arch \(g f e\) ready to zeceive it. And thus the vibration of the balance will be continued.

From the above detcription we may deduce the pro. per dimenfions of the farts of the pallet. 'Ihus, the length of the pallet \(c d\) or \(g h\), muft be equal to the interval between two fucceeding pins, and the diflance of the centres DE, muft be double of that interval. The radius \(\mathrm{D} e\) or \(\mathrm{E}_{g}\), may be as fmall as we choofe. The concave arches \(c b a\) and \(g f e\), muft be continued fo far as to allow a pin to retl on them during the whole exchafion of the balance. The angle of fcapement, in which the balance remains under the influence of the wheels, is obtained by drawing the lines \(\mathrm{D} c\) and \(\mathrm{D} d\), and we thall find that this anglec \(\mathrm{D} d\) is here about \(30^{\circ}\), though it may be made either greater or lefs than this.

Fig. 19. explains how the two pallets may be com- Fig. Ps, bined on one verge. KL is the verge with a pivot at each end. It is bent like a crank MNO, to admit the balance wheel between its branches. BC reprefents this wheel, feen edgewife, with its pir alternately on different fides. The pallets are alfo reprefented by \(b c d\) and \(k g f\), fized to the infide of the branches of the crank, fronting tach other. The pofiton of their acting faces may be feen in the preceding figure, on the verge D , where the pallet \(g h\) is reprefented by the dotted line \(2 i^{i}\), as fiuated behind the pallet \(c d\). The remote pallet \(2 i\) is fo placed, that when the point \(d\) of the near pallet is quitted by a pin 1 on the upper fide of the wheel, the angle formed by the face a:d the atch of reft of the other pallet is juit ready to receive the next pin 2, which lies on the lower fide of the rim. It is plain that the action here will be the fame as if the pallets mere on feparate axes. The pin 1 efcajes from \(d\), and the pin 2 is received on the arch of refl, and locks the wheel, while the balance continues in motion. When the balance returns, 2 gets of the arch of reft, puftes afide the palles \(2 i\), efcapes from it when \(i\) gets to \(I\), and then the point \(c\) is ready to receive the pin \(3, \& c\). The vibrations may be increafed by giving a fufficient impulfe through the angle of fapement, but they camot exceed a certain quantity, othervile N , the top of the crank, would frike the tim of the wheel. The vibrations may be eafily increafed to \(180^{\circ}\), by placing the pins at the very edge of the wliecl; and by placing them at the points of long teeth, fo that the crank may get in between them, the vibrations may be carried to a much greater extent.

The conftruction juft deferibed is exceedingly ingeniious; and if the machinery be well executcd, this fcaplement will excel the hoisiomal feapement of Graham, bools as it has but two acting faces to form, and as it ad. mits of making the rircle of rcft exiremely fmall, without leffening the acting facc of the pallet. The conflruction is, however, very delicate and difficult, and mull require a vory nice workman.

\section*{W A T [ 647 ] W A T}
ching, An excellent fcapement of much more eafy conftruc. ater. tion, is that commonly called Duplaie's foapement, and with this we thall conclude our account of watch-work. Fig, 20. reprelents the effential parts fomewhat magnified. AD a portion of the balance-wheel, having teeth \(f, h, g\), at the circumference. Thefe teeth are for pro- ducing the refl of the wheel, while the balance is making excurfions beyond the liapement. This is affected by an agate cylinder \(s p g\), on the verge. 'This cylinder has a noteh 0 . When the cylinder turns round in the dircetion opg, the notch eaflly paffes the tooth \(B\) which is refling on the cylinder lurface; but when it returns in the direction qpo, the tooth B gets into the notch, and follows it, pretling on one fide of it till the notch comes into the pofition 0 . The tooth being then in the polition \(h\), efcapes from the notch, and another toctly drops on the convex furface of the cylinder at B . The ba-lance-wheel is allo furnithed with a fit of flat-fided pins, flanding upright on its rim reprefented by a D. There is likewilc fixed on the verge a larger cylinder GFC above the finaller one opq, with its lower furface clear of the whecl, and having a pallet \(C\), of lapphire, firmly indented into it, and projecting fo far as to keep clear of the pins on the wheel. The pofition of this cylinder, with refpect to the fmaller one below it, is fuch that the looth \(b\) being efcaped from the notch, the pallet C has jult patt the pin \(a\), which was at A while B relted on the fmall cylinder; but it moved from A to \(a\), while B moved to \(b\). The wheel being now at liberty, the pin \(a\) exerts its prefure on the pallet \(C\) in the moit direct manner, and gives it a ftrong impulfion, following and accelerating it till another tooth flops on the little cylinder. The angle of fcapement depends partly on the projection of the pallet, and partly on the diameter of the fmall cylinder, and the advance of the tooth B into the notch. Independent of the action on the fmall cylinder, the angle of fcapement would be the whole arch of the larger cylinder between C and \(\%\). But a ftops before it be clear of the pallet, and the arch of impulfion is thot tened by all the fpace defcribed by the pin while a tooth moves from \(B\) to \(b\). It ftops at \(d\).

For an account of other feapements we muft refer our rcaders to the Menoirs of the A-ademy of Sciences at Paris for 1748 , Cumming's Elentents of Clack and Watchwork, a Erench work entitled Machines approuvées par 'Academie des. Sciences, and Young's Lectures on Naturat Philofopluy, vol. i. p. 193, and Plate 16, vol. ii. p. 193.

WATCHING, in Medicine, is when the patient caunst fleep. In fevers it is a dangerous fymptom, and if long continued ends in a deliriun.

WATER, a well known flid, diffufed through the atmofp!ere, and over the furiace of the globe, and abounding in a certain proportion in animals, vegetab!es, and minerals.

The ufes of water are fo univerfally known, that it would be fuperflous to enumerate them in this article. It is effential to anim land vergtable lite; it makes ealy the intercourfe between the mont diftant regions of the world; and it is one of the moft ufeful powers in the mechanic arts. It is often found combined with varicus fubfances, and is then frequentiy beneficial in curing or alleviating difeafes.

Thole propertics of water which fit it for anfwering mechanical purpoles are explained in other articles cs
this Work (fee Hidrodynamics, Pneumatics, No 3. Resistance, and Rivers) ; and for the difcuvery of the compolition of water, lee Chbmistry Index.

Mineral WATERS. For the method of analyfing them, fee allo Chemistry Index.

Under the title of MIN:RAS Waters, we have given an analyfis of the molt remarkable wa:ers in Europe.

Holy WATER, which is made ufe of in the church of liome, as alfo by the Greeks, and by the other Chriflians of the Liaft of all denominations, is water with a nixture of falt, bleffed by a prieft according to a fet form of benediction. It is ufed in the bleffing of perfons, things, and places; and is likewife confidered as a ceremony to excite pious thoughts in the minds of the faithful.
'The priefts, in bleffing it, firft, in the name of God, commands the devils not to hurt the perfons who thall be [prinkled with it, nor to abufe the things, nor difquiet the places, which flall likewife be to fprinkled. He then prays that health, fafety, and the favour of henven, nay be enjoyed by luch perfons, and by thofe who thall ule fuch things, or dwell in fuch places. Veftments, vellels, and other fuch things that are fet apart for divine fervice, are furinkled with it. It is fometimes fprinkled on cattle, with an intention to free or preferve them from diabolical enchantments; and in fome ritual books there are prayers to be faid on fuch occafions, by which the fafety of fuch animals, as being a temporal bleffing to the poffeffors, is begged of God, whofe providential care is extended to all his creatures. The hope which Catholics entertain of obtaining fuch good effects from the devout ufe of holy water, is grounded on the promife made to believers by Chrift (St Mark xvi. 17.), and on the general efficacy of the prayers of the church; the petition of which prayers God is often pleafed to grant; though fometimes, in his Providence, he fees it not expedient to do fo. That fuch effeets have been produced by holy water in a remarkable manner, has been afferted by nany authors of no fmall weicht; as, namely, by St Epiphanius, Haer. \(32 \mathrm{th}_{1}\); St Hierom, in the Life of St Hilarion; Theodoret Hijl. Eccl. lib. v. cap. 21.; Palladius, Mifl. Lauf; Bede, lit. r. cap. 4 .

As a ceremony (fays the Catholic), water brings to our remembrance our baptifm ; in which, by water, we were c!canfed from original fin. It alfo puts us in mind cf that purity of confcience which we ought to endeavour always to have, but elpecially when we are going to worthip our God. The falt, which is put into the waier to preferve it from corrupting, is alfo a figure of divine grace, which preferves our fouls from the corruption of fin; and is likemife an cinblem of that wifdom and difcretion which ought to feafon every action that a Chriltian docs, and every word that he fays. It is wont to be bleffed and fprinkled in churches on Sundays, in the beginning of the folemn office. It is kept in veflels at the doors of the fame churches, that it may be taken by the faithful as they enter in. It is allo often kept in private houres and cliambers.

Putrid WATER, is that which has acquired ain offenfive fmell and tafie by the putrefcence of animal or vegetable fubfances contained in it . It is in the highent desree pennicious to the human frame, and capable of bringing on mortal difeafes even by its fmell. It is not always sroa the apparent muddinefs of waters than we
can juidge of their difpofition to puttefy; fome which are feemingly very purc being more apt to become puirid than others which appear much more mixed with heterogeneous matters. Under the article Animalcule, No 33 , is mentioned a fpecies of infects which bave the property of making water ftinls to an incredible degree, though their bulk in proportion to the tluid which lirrounds them is lefs than that of one to a million. Other fubflances no doubt there are which have the fame proprity; and hence almolt all water which is confined from the air is apt to become offenfive, even though kept in glafs or fluneware veliels. Indced it a common oblervation, that water keeps much longer fiveet in glafs vellels, or in thofe of earthen or foneware, that in thofe of wood, where it is exceedingly apt to putrefy. Hence, as hrips can only be fupplied with water kept in wooden cafks, failors are extremely liable to thofe difcafes which arife from purid water; and the difcovery of a method by which water could eafily be prevented f:om becoming putrid at fea would be exceedingly valuabre. This may indeed be done by quicklime; for when water is impregnated with it, all putrefecnt matters are either totally deftroyed, or altered in fuch a manner as never to be capable of undergoing the putrefuctive fermentation again. But a continued ufe of limewater could not fail of being pernicious, and it is therefore neceflary to throw down the lime; after which the water will have all the purity necefiary for preferving it free from purefaction. This can only be done by means of fixed air; and mere expofure in broad fhallow veffels to the atmofphere would do it without any thing elfe, only taking care to break the crult which formed upon it. Two nuethods, however, have been thought of for doing this with mure expedition. The one, invented by Dr Alton, is, by throwing into the water impregnated with lime a quantity of magnefia. The lime attracts fixed air more powerfully than magnefa; in confequence of which the latter parts with it to the line : and thus becoming infoluble, falls along with the cautic magnefia to the bottom, and thus leaves the water perfeetly pure. Another method is that of Mr Henry, who propofes to throw down the lime by means of an effervefcing misture of oil of vitriol and chalk put down to the bettom of the water caf. His appatatus for this purpofe is as fimple as it can well be made, though it is hardly probabie that failors will give themfelres the trouble of ufing it; and Dr Alitors's Icheme would feem better ealcula? ed for them, were it not for the expence of the magnefia; which indeed is the only objection made to it by Mr Henry. Putrid water may be rellored and made potable by a procefs of the fame kind.
Of late it has been difcovered that charcoal poffeffes many unexpected propertie, and, among othere, that of preferving water from corruption, and of purifying it after it has been corrupted. Mr Lowitz, whofe experiments on charcoal have been publiflied in Crell's Cheinical Joumal, has turned his attention to this fubject in a memoir read to the Economical Socicty at Peterf: burgh. He forsnd that the effect of charcoal was rendered much more fpeedy by ufing along with it fome fulphuric acid. One ounce and a half of charcoal in powder, ard 24 drops of concentrated fulphuric acid (oil of vitriol), are fuflicient to purify three pints and a half of corrupted water, and do not communicate to it ary fenfible acidity. This fmall quantity of acid renders
it unneceflary to ufe more than a third part of the char coal punder which would otherwife be wanied; and the lefs of that porder is employed, the lefs is the gunanlity of water lott ly the operation, which, in fea-wpages, is an olject wordny of confideration. In prepertion to lise quantity of acid made ufc. of, the quanity of charceal may be diminilhed or augmented. All acids produce rearly the fame eficcts: neutral falts allo, particularly nitre and fea falt, may be ufel, but fulphuric acid is ple. ferable to any of thele; water which is puriticd by means of this asid and chareval will keep a longer time than that which is purified Ly clarcoal alone. When we mean to puify any given quantily of comupted water, we thould begin by adding to it as much powder of charcoal as is neceffary to deriive it entircly of iss bad fmell. 'To afcertain whether ihat quantity of pordered charcoal was fufficient to effeet the clarification of the faid water, a fmall qquantity of it may be paffed through a linen bag, two or three inches long; it the water, thus filtrated, fill has a turbid appearance, a frefl qua:! tity of powdered charcoal muft be added, till it is become perfectly c!ear: the whole of the water may then be paffed through a filtering bas, the fize of which hotild be propostioned to the guantity of water. If fulphuric acid, or any other, can be procured, a fmall quanlity of it hould be added to the water, before the clarcoal powder

The cleaning of the cafks in which water is to be kept in fea-voyages thould never be neglected: they thould be well waihed with hot water and fand, or with any other fubtance capable of remorirg the mucilaginous particles, and afterwards a quantity of charceal dutt thouid be employed, which will entirely deprive them of the mufty or putrid fmell they may have con-tracted.-The charcoal ufed for purilying water floculd be well burrt, and afterwards beat into a fine powder.

Sea-IVATER. See SEA-WGter.
WATER-Caris, carriages confructed for the purpofe of watering the roads for feveral miles round L.ondon; a precaution abfolutely neceflary near the metropolis, where, from fuch a valt daily influs of carriages and horfes, the dift would otherwife become quite infufterable in hot dry weather. Pumps are flaced at proper ditances to fupply thete calts.

\section*{Thiler. Ordenl. Sce Ordeal.}

Water, anong jewellers, is properly the colour or luftre of dian:onds and pearls. The term, though lefs properly, is fometimes ufed for the hue or colcur of other ftones.

Vater-Bellows. See Machines for blowing Air into FURNACES.
WafEr-Coloars, in Painting, are fuch colours as are only diluted and mixed up with gum-riater, in contradiftinction to oil-coluurs. See COLOUR-Making.
IVATER-Gang, a channel cut to drain a place by carrying off a Itream of waler.

IVater-Hen. See Parri, Ornitholociy Index.
\(W_{\text {ATE }}\)-Lines of a Ship, certain horizuntal lines fuppofed to be drawn about the outfide of a'flip's boltom, clofe to the furface of the water in which fire floats. They are accordingly higher or lower upon the bottom, in proportion to the depth of the columu of water required \(10^{\circ}\) float her.
WATER-Logged, the ftate of a hip when, by receiving a gieat quantily-of water into the hold, by leaking, \&c.

the has become heavy and inactive upon the fea, fo as to yield without refiltance to the efforts of every wave rulhing over her decks. As, in this dangerous fituation, the centre of gravity is no longer fixed, but fluctuating from place to place, the Itability of the lhip is utterly lolt : the is therefore almof totally deprived of the ufe of her fails, which would operate to overfct her, or prefs the head under water. Hence there is no refource for the crew, except to free her by the pumps, or to abandon her by the boats as foon as pollible.

Water-Sail, a fmall fail fpread occafionally under the lower ftudding-fail, or driver-boum, in a fair wind and fmooth fea.

Water-Ouzel. See Turdus, Ornithology Index.
WATER-Spout, an extraordinary meteor, confifting of a large mals of water collected into a fort of column, and moved with rapidity along the furface of the fea.

The beft account of the water-fpout which we have met with is in the Phil. Tranf. Abridged, vol. viii. as oblerved by Mr Jofeph Harris, May 21. 1732 , about funfet, lat. \(32^{\circ} 30^{\prime} \mathrm{N}\). ; long. \(9^{\circ} \mathrm{E}\). from Cape Florida.
"When firt we faw the fpout (fays he), it was whole and entire, and much of the fhape and proportion of a fpeaking trumpet; the fmall end being downwards, and reaching to the fea, and the big end terminated in a black thick cloud. The fpout itfelf was very black, and the more fo the higher up. It feemed to be exaetly perpendicular to the horizon, and its fides perfectly fmooth, without the leaft ruggednels. Where it fell the fpray of the fea rofe to a confiderable height, which made fomewhat the appearance of a great fmoke. From the firft time we faw it, it continued whole about a minute, and till it was quite diffipated about three minutes. It began to wafte from below, and fo gradually up, while the upper part remained entire, without any vifiblc alteration, till at laft it ended in the black cloud above; upon which there feemed to fall a very heavy rain in that neighbourhood. - There was but little wind, and the fky elfewhere was pretty ferene."

Water-fpouts have by fome been fuppofed to be merely electrical in their origin; particularly by Signior Beccaria, who fupported his opinion by fome experiments. But if we attend to the fucceffive phenomena neceffary to conftitute a complete water-fpout through their various flages, we fhall be convinced, that recourfe muft be had to fome other principle in order to obtain a complete folution.
D. Franklin, in his Phyfical and Meteorological Obfervations, fuppofes a water-fpout and a whirlwind to proceed from the fame caufe; their only difference being, that the latter palles over the land, and the former over the water. This opinion is corroborated by M. de la Pryme, in the Philofophical Tranfactions, where he deferibes two fpouts oblerved at different times in York. fhire, whole appearances in the air were exactly like thofe of the fpouts at fea, and their effects the faine as thofe of real whirlwinds.

A fluid moving from all points horizontally towards a centre, mult at that centre either mount or defcend. If a hole be opened in the middle of the bottom of a tub filled with water, the water will flow from all fides to the centre, and there defcend in a whirl: but air flowing on or near the furface of land or water, from all fides towards a centre, muft at that centre afcend; becaufe the land or water will hinder its defcent.

Vol. XX. Part II.

The doctor, in proceeding to explain his conceptions, begs to be allowed two or three pofitions, as a fuunda. tion fur his hypothefis. I. '1lat the lower region of air is often more heated, and fo more rarefied, than the upper, and by confequence fpecifically lighter. The coldnefs of the upper region is manifelted by the hail, which falls from it in warm weather. 2. That heated air may be very moilt, and yet the moilture fo equally diffufed and rarefied as not to be vifible till colder air mixes with it; at which time it condenfes and becomes vifible Thus our breath, although invifible in fummer, becomes vifible in winter.

Thele circumftances being granted, he prefuppofes a tract of land or fea, of about 60 miles in extent, unfheltered by clouds and unrefrefhed by the wind, during a fummer's day, or perhaps for feveral days without intermillion, till it becomes violently heated, together with. the lower region of the air in contact with it; fo that the latter becomes fpecifically lighter than the fuperincumbent higher region of the atmofphere, wherein the clouds are ufually floated: he fuppofes alfo that the air furrounding this tract has not been fo much heated during thole days, and therefore remains heavier. The confequence of this, he conceives, fhould be, that the heated lighter air hould afcend, and the heavier defcend; and as this rifing cannot operate throughout the whole tract at once, becaule that would leave tos extenfive a vacuum, the rifing will begin precifely in that column which happens to be lightelt or moft rarefied; and the warm air will flow horizontally from all pats of this column, where the feveral currents meeting, and joining to rife, a whirl is naturally formed, in the fame manner as a whirl is formed in a tub of water, by the defcending fluid receding from all fides of the tub towards the hole in the centre.

And as the feveral currents arrive at this central rifing column with a confiderable degree of horizontal motion, they cannot fuddenly change it to a vertical motion: therefore as they gradually, in approaching the whirl, decline from right to curve or circular lines. fo, having joined the whirl, they afcend by a firal motion; in the fame manner as the water defcends firally through the hole in the tub before mentioned.

Laftly, as the lower air neareft the furface is more rarefied by the heat of the fun, it is more impreffed by the current of the furrounding cold and heavy air which is to aflume its place, and confequently its motion towards the whirl is fwiftelt, and fo the force of the lower part of the whirl ftrongelt, and the centrifugal force of its particles greateft. Hence the vacuum which inclofes the axis of the whirl hould be greatelt near the earth or fea, and diminih gradually as it approaches the region of the clouds, till it ends in a point.

This circle is of various diameters, fometimes very large.

If the vacuum paffes over water, the water may rife in a body or column therein to the height of about 32 feet. This whill of air may be as invifible as the air itfelf, though reaching in reality from the water to the region of cool air, in which our low fummer thunderclouds commonly fioat; but it will foon become vifible at its extremities. The agitation of the water under the whirling of the circle, and the fwelling and rifing of the water in the commencement of the vacuum, renders it viffible below. It is perccived above by the
warc:

Water-
fpout.

Tratior- warm air being brought up to the cooler region, where its moiflure begins to be condenfed by the culd into thick vapour, and is then frit difcovered at the higheft
part, which being now cooled condenles what rifes behind it, and this latter aEis in the fame minner on the fucceeding body; where, by the contact of the vapours, the cold operates fafter in a right line downwards, than the vapours themfelves can climb in a firial line upwards: they climb however ; and as by continual actdition they grow denfer, and by confequence increafe their centrifugal force, and being rifen above the concentrating currents that compoie the whirl, they fly off, and form a cloud.

It feems eafy to conceive, how, by this fuccefive condenfation from above, the §pout appears to drop or defcend from the cloud, although the materials of which it is compofed are all the while afcending. The condenfation of the moiflure contained in fo great a quantity of warm air as may be fuppofed to rife in a fhort time in this prodigioufly rapid whirl, is perhaps fufficient to form a great extent of cloud; and the friction of the whirling air on the fides of the column may detach great quantities of its water, difperfe them into drops, and carry them up in the firal whirl mised with the air. The heavier drops may indeed fly off, and fall into a fhower about the fpout; but much of it will be broken into vapour, and yet remain vifible.

As the whirl weakens, the tube may apparently feparate in the middle; the column of water fubfiding, the fuperior condenfed part drawing up to the cloud. The tube or whiril of air may neverthelefs remain entire, the middle only becoming invifible, as not containing any vifible matter.

Dr Lindfay, however, in feveral letters publifhed in the Gentleman's Magazine; has controverted this theory of Dr Franklin, and endeavoured to prove, that waterapouts and whirlwinds are difinet phenomena ; and that the water which forms the water \{pour, does not afcend from the fea, as Dr Franklin fuppofes, but defeends from the atmofiphere. Our limits do not permit us to infert his arguments here, but they may be feen in the Gentleman's Magazine, volume li. p. 559, 6is; vol. liii. F. 1025 ; and vol. lv. p. 594. We cannot avoid ohferving, however, that he treats De Franklin with a degree of afperity to which he is by no means entitled, and that his arguments, even if conclufive, prove nothing more than that fome water-fpouts certainly defcend; which Dr Franklin hardly ever ventured to deny. There are fome very valuable differtations on this fubject bv Profefior Wilcke of Upfal.
- IVATFR Works. Under this name may be comprehended almoft every hydraulic fructure or contrivance ; fuch as, canals, conduits, locks, mills, water engines, \&cc. But they may be conveniently art ?nged under two general heads, ift, Wooks which have for their object the conducting, raifing, or otherwife manating, of water; and, 2diy, Works which derive their cficary from the impulfe or other action of water. The firf clafs compreliends the methods of fimply conducting water in aqueducts or in pipes for the fupply of domentic confumption or the working of machinery : It comprehends alfo the methods of procuring the fupplies neceffary for thefe purpofes, by means of pumps, water, or fire engines. It alfo comprechends the fub-

Sequent managenent of the water, thus conduced, whether in order to make the proper diffribution of it accosding to the demand, or to employ it for the purpole of navigation, by lockage, or other contrivances. -And i:s the profecution of thefe things many fuhordinate problems will occur, in which prastice will derive great advantages from a fcientific acquaintance with the fiubject. The fecond clafo of water-works is of much greater variely, comprehending almoft every kind of hydraulic machine; and would of itfelf filt volumes. Many of thefe have already occurred in varicus articles of this Dictionny. In defcribing or treating then, we have tacitly riferred the difcuffion of their general princifles, in which they all relembee each other, to fome article where they could be taken in a connected body, fufceptible of sreneral fcientific difcuffion, independent of the circumflances which of neceflity introduced the particular modifications required by the ufes to which the flrulutes were to be applied. That part of the prefent article, therefore, which embraces thefe common principies, wifl cliefly relate to the theory of water mills, or rather of water wheefs; becaufe, when the necciary motion is given to the anis of the water wheel, this may be fet to the performance of any taik whatever.

\section*{CLASS I.}

\section*{1. Of the conducting of Water:}

This is undoubtedly a bufineis of great importance, and makes a pincipal part of the praclice of the civil engineer: It is alfo a bufinefs fo imperfectly underifood, that we believe that very few engineers can venture to fay, with tolerable precifion, what will be the quantity of water which his work will convey, or what plan and dimenfions of conduit will conver the quantity which may be propofed. For proof of this we thall only refer our readers to the fachs mentioned in the aricle RIvers, \(\mathbb{N}^{\circ} 2 \%\), \&ic.

In that article we have given a fort of hiftory of the progrefs of our knowledge in hydraulics, a branch of mechanical philofophy which feems to have been entircly unknown to the ancients. Even Archimedes, the author of almoft all that we know in hydroftatics, feems to have been entirely ignorant of any principles ty which he could determine the motion of water. The mechanical fcience of the ancients feems to have reaci:no farther than the doctrine of equilibrium among bodies at refl. Guglielmini firf ventured to conlider the motion of water in open cansls and in rivers. Its motion in fipes had been partially confidered in detached fcraps by others, but not fo as to make a boly of doctrine. Sir Ifaac Newton firf endentoured to render hydraulics fufeeptible of mathematical demonAration: But his fundamental propofition has not yet been fieed from very ferious oljections; nor have the attempts of his fucceffors, fuch as the Bernoullis, Euler, D'Alembert, and others, been much more fucceffful: fo that hydraulics may fill be confidered as very imlerfeet, and the general conclufions which we are accuftomed to receive as fundamental propofitions ane not much better than matters of obfervation, little fupported by principle, and therefore requining the noff frupu-

\section*{TV A T [ 651 ] W A T}

Watcrworks.
lons caution in the application of them to aay hitherto intried cafe. When experiments are mulitplied fo as to include as great a variety of cafes as poffible ; and when thefe are cleared of extraneous circumallances, and properly arranged, we mul receive the conclulions drawn from them as the general laws of hydraulics. The experiments of the abté Bofiut, narrated in his Ihy \(^{\text {a }}\) drodynamique, are of the greatelt value, having been made in the cales of molt general frequency, and being made with great carc. The greate!t forvice, however, has been done by the cheralicr Puat, who faw the folly of attempting to deduce an accurate theory from any principles that we have as yet lcarned, and the neceffity of athering to fuch a theory as could be deduced from cxperiment alone, independent of ahy more general principles. Such a theury mut be a jull one, if the experiments are really general, unafected by the particular circumilances the cale, and if the claffes of experiment are fufficiently cemprehenfive to include all the cafes which occur in the moll important prattical quellions. Sume principle was neceflary, however, for connecting thefe experments. The fufficiency of this principle was not eafily afcertained. M. Buat's way of eftablilhirg this was judicious. If the principle is illfounded, the refules of its combination in cafes of actual experiments mut be irregular; but if experiments, feemingly very unlike, and in a vaf variety of diffimilar cafes, give a train of refults which is extremely regular and confiltent, we may prefume that the principle, which in this manner harmonizes and reconciles things fo unlike, is founded in the nature of things; and if this principle be fuch as is agreeable to our cleareft notions of the internal mechanifm of the motions of fluids, our prefumption approaches to conviction.

Proceeding in this way, the chevalier Buat has collected a prodigious number of facts, comprehending almoll every cafe of the motion of Aluds. He firt claffed them according to their refemblance in fume one particular, and obferved the diferences which accompanied their differences in other circumflances; and by confidering what could produce thefe differences, he obtained general rules, deduced from fart, by which the fe differences could be made to fall into a regular feries. He then arranged all the experiments under fome other circumftances of refemblance, and purfued the fame method; and by following this out, he has produced a general propofition, which applies to the whole of this
numerous lif of experiments with a precifion far excced. ing our utinof hopes. This propofition is contained in \(\mathrm{N}^{2} 59\). of the articie Riverss, and is there offered as

Waterwoiks. one of the moll valuable refults of modern feience.

We mun, however, ubierve, that of this lit of experiments there is a very large clafs, which is not direct, but requires a good deal of rellection to enable as to draw a confident conclufion; and this is in cafes which are very frequent and important, viz. where the declivity is excecdingly fmall, as in open curals and rivers. The experiments were of the folluwing furms: Irwo large cifterns were made to communicate with each other by means of a pipe. 'The furfaces of the water in thele ciftens were made to differ only by a fmall liaction of an inch : and it is fuppofed that the motion in the communicating pipe will be the fame as in a very long pipe, or an open canal, laving this very minute declivity. We have no difficulty in admitting the conclufion; but we have feen it contefled, and it is by no means intuitive. We had entertained hopes that this important cafe would have been determined by direft experiments, which the writer of this aricle was commiffuned to make by the Board for Encouraging Improvements and Manufactures in Scolland: But the infrom Aate of his health was always an effectual bar to the accomplilment of this defirable object. 1his, however, need not occafion any hefitation in the adoption of M. Buat's gencral propofition, becaufe the experiments which we are now criticiling fall in precifely with the general train of the relt, and fhow no general deviation which would indicate a fallacy in principle.

We apprehend it to be quite unneceflary to add much to what has been already delivered on the motion of waters in an open canal. Their general progrefive motion, and confequently the quantity delivered by an aqueduct of any flope and dimenfion, are fufficiently determined; and all that is wanted is the tables which we promifed in No 65 . of the article Rivers, by which any perfon who underfands common arithmetic may, in five minutes time or lefs, compute the quantity of water which will be delivered by the aqueduct, canal, conduit, or pipe; for the theorem in \(\mathrm{N}^{\circ} 59\). of this article applies to them all without diftinction. We therefore take this opportunity of inferting thefe tables, which have been computed on purpofe for this work. with great labour.
V. A T

\section*{W A T}

Waterwork:

Table I. confitts of three columns.-Column I. entitled \(d\), contains the hy draulic mean depths of any con. duit in inches. Ihis is fet down for every 10 th of an inch in the firtt 10 inches, that the antivers may be more accurately ubtained for pipes, the mean depth of which feldom exceeds three or four inches. The column is continued to 100 inches, which is fully equal to the hydraulic mean depth of any canal.

Column 2. contains the logarithms of the values of \(\sqrt{ } d-0.1\), multiolied by 357 ; that is, the logarithm of the numerator of the fraction \(\frac{307(1 / d-0.1)}{\sqrt{s-1} \sqrt{s+1.6}}\) in \(N^{0}\) 65. of the article Rivers.

Culumn 3. contains the produet of the values of \(\sqrt{d}-0.1\) multiplied by 0.3
Taele II. confints of two columns.-Column 1. entitled \(s\), contains the denominator of the fraction exprefsing the flope or declivity of any pipe or canal ; that is, the quosient of its length divided by the eleration of onc extremity above the other. Thus, if a canal of one mile in length be three feet highier at one end than the other, then \(s\) is \(\frac{5280}{3}=1 \geqslant 60\).

Column 2. contains the logarithms of the denominators of the above mentioned fraction, or of the different values of the quantity \(\sqrt{s-L \sqrt{s+1.6}}\)

Thefe quantities were computed true to the third decimal place. Notwithlanding this, the laft figure in about a dozen of the firt logarithms of each table is not abfolutely certain to the neareft unit. But this cannot produce an error of \(1 \mathrm{in} 100,000\).

\section*{Examples of the UYe of the fe Tables.}

Example 1. Water is brought into the city of Edinburgh in feveral mains. One of thefe is a pipe of five inches diameter. The length of the pipe is 14.637 feet; and the refervoir at Comition is 44 feet higher than the refervoir into which it delivers the water on the Cafte Hill. Query, The number of Scotch pints which this pipe fhould deliver in a minute?
1. We have \(d=\frac{5}{4}\), \(=1.25\) inches. The logarithm correfponding to this \(d\), being nearly the mean between the logarithms correfponding to 1.2 and 1.3 is 2.49472.
2. We have \(s=\frac{14637}{44}\), or 332.7 . The logarithm correfponding to this in Table II. is had by taking proportional parts for the difference between the logarithms for \(s=33 \circ\) and \(s=342\), and is 1.18533 .
\[
\begin{array}{ll}
\text { 3. From } & 2.49472 \\
\text { Take } & 1.18533
\end{array}
\]

Remains 1.30939 , the logarithm of 20.385 inches.
4. In column 3. of Table I. oppofite to \(d=1.2\) and \(d=1.3\) are 0.3 and 0.31 , of which the mean is 0.305 inches, the correction for vifcidity.
5. Therefore the velocity in inches per fecond is \(20.385-2.305\), or 20.08 .
6. To obtain the Scolch pints per minute (each containing 103.4 cubic inches , multiply the velocity by 60 , and this produet by \(5^{2}\), and this by 0.7854 ( the
area of a circie whofe diameter is 1 ), and divide by 103.4. Or, by logarithms,
wurk.

Example 2. The canal mentioned in the article Rivers, \(\mathrm{N}^{\circ} 6_{3}\). was 18 feet broad at the furface, and 7 feet. at the bottom. It was 4 feet deep, and had a declivity of 4 inches in a milc. \(\underbrace{}_{\mathrm{Qucry}}\), The mean velocily?
1. The flant fide of the canal, correfponding to 4 fect deep and \(5 \frac{3}{2}\) projechion, is 6.8 feet ; theiefore the border touched by the water is \(6.8+7+6.8,=20.6\). The area is \(4 \times \frac{18+7}{2}=50\) fquare fect. Therefore \(d=\) \(\frac{50}{20.6},=2.427\) feet, or 29.124 inches. The logarithm correfponding to this in Table I. is 3.21113 , and the correction for vilcidity from the thiid culum of the fame Table is I .58.
2. The llope is one-third of a foot in a mite, or one foot in three miles. Therefores is \(15.8_{4} 0\). The logarithm correfponding to this is 2.08280 .
```

3. From 3.211I3
Subtract 2.0S280
Remains 1.12833=log. of 13.438 inclies.
Subtract for vifcicity
Velocity per fecond
II.858
```

This velocity is confiderably fmaller than what was obferved by Mr Watt. And indeed we obferve, that in the very fmall declivities of rivers and canals, the formula is a little different. We have made feveral comparifons with a formula which is effentially the fame uith Buat's, and comes neares in thefe cafes. Inftead of taking the hyperbolic logarithm of \(\sqrt{s+1.6}\), multiply its common logarithm 1 y \(2 \frac{1}{1}\), or multiply it by 9 , and divide the product by 4 ; and this procels is vattly eafier than taking the hyperbolic logarithm.

We have not, however, prefumed to calculate tables on the authority of our own obfervations, thinking 100 refpectfully of this gentleman's labours and oblervations. But this fubject will, ere lung, be fully eftablifled on a feries of obfervations on canals of various dimenfions and declivities, made by feveral eminent engineers during the execution of them. Fortunately Mr Buat's formula is chiefly founded on obfervations on fmall canals; and is therefore moft accurate in fuch works where it is moft neceflary, viz. in mill courfes, and other derivations for working machinery.

We now proceed to take notice of a few circumftances which deferve attention, in the conftruation of canals, in addition to thofe delivered in the article Rivers.

When a canal or aqueduet is brought off from a bafon

\section*{W A T [ 6.5\(]\) W A T}
or lariver Aleam, it ought always to be widened at the entry, if it is intended for drawing of a consinued ftream of water: For fucla a canal has a flope, without ishich it can have no current. Suppofe it filled to a ofad level to the fatther cod: Take away the har, and the water inmediately begins to flow off at that ond. Sut it is fome tine before any motion is perceived at the head of the canal, during all which time the motion of the water is zugmenting in every part of the canal; conlequently the llope is increaling in every part, this being the fole caufe of its flrean. When the water at the entry begins to move, the \(\mathrm{fl}_{\mathrm{jp}} \mathrm{p}\) is farcely fenfible there; but it fenfibly fteepens every moment with the increafe of velocity, which at laft attains its maximum relative to the flope and dimenfions of the whole canal ; and this regulates the depth of water in every point dowa the fiream. When all has attained a flate of permanency, the llope at the eatry remains much greater than in any other part of the canal ; for this thope muft be fuch as will produce a velacity fufficient fur fupplying its TRANS.

And it muft be remembered, that the velocity which muft be produced greatly esceeds the mean velocity correfponding to the train of the canal. Suppofe that this is 25 inches. There muft be a velocity of 30 inches at the furface, as appears by the Table in the article RIvers, \(N^{\circ}\) So. This mult be produced by a real fall at the entry.

In every otier part the flope is fufficient, if it mercly ferres to give the water (already in motion) force enough for nerercoming the friction and other refiftances. But at the entry the water is flagnant, if in a bafon, or it is moving paft laterally, if the aqueduct is derived from a river; and, having no velocity whatever in the direction of the canal, it mult derive it from its flope. The water therefore which has acquired a permanent form in fuch an aqueduct, mufl neceflarily take that form rent portions. The furface remains horizontal in the bafon, as to KC (fig. r.), till it comes near the entry of the canal \(A B\), and there it acquires the form of an undulated curve CDE ; and then the furface acquires an uniform flope EF, in the lower part of the canal, where the water is in train.

If this is a drain, the difcharge is much lefs than might be produced by the fame bed if this fuddeu flape could be avoided. If it is to be navigated, having only a very gentle flope in its whole length, this fudden flope is a very great imperfection, both by diminifhing the depth of water, which might otherwife be obtained along the canal, and by rendering the pafiage of boats into the bafon very difficult, and the coining out very hazardous.

All this may be avoided, and the velocity at the entry may be kept equal to that which forms the train of the canal, by the fimple procefs of enlarging the entry. Suppofe that the water could accelerate along the flopes of the canal, as a heary body would do on a finely polifhed plane. If we now make the width of the entiy in its different parts inverfely proportional to the fictitious velocities in thofe parts; it is plain that the flope of the furface will be made parallel to that of the canal which is in train. This will require a form fomewhat iike a bell or fpeaking trumpet, as may eafily be flown liy a mathematical difcuffion.... It would, however, be
fo much crafated at the bafon as to occupy natech soom, and it would be very expenfive to make luch an exca. vation. But we may, at a very nouderate expence of money and room, make the increafe of velocily at the entry almoft infenfible. This hould always be dune, and it is not all expence: for if it be not done, the water will undermine the banks on each fide, becaufe it is moving very fwifty, and will make an excavation for iifelf, leaving all the mud in the canal below. We may oblerve this enlargement at the entry of all watural derivations from a balon or lake. It is a very inilructive experiment, to fill up this enlargoment, continuing the parallel fides of the drain quite to the fide of the lake. We Aall immediately obfetve the water grow flallower in the drain, and its performance will diminifh. Suppofing the ditch carried on with parallel fides quite to the fide of the bafon, if we build two walls or dykes from the extremities of thofe fides, bending nutwards with a proper curvature (and this will often be lefs contly than widening the drain), the difcharge will be greatly increafed. We have feen inflances where it was nearly doubled.

The enlargement at the mouths of rivers is generally owing in the fame caufe. The tide of flood up the river produces a fuperficial flope oppofite to that of the river, and this widens the mouth. This is mof remarkable when the tides are high, and the river has littie flope.

After this great fall at the entry of the canal, in which all the filaments are much accelerated, and thie inferiar ones moft of all, things take a cuntrary turn. The water, by rubbing on the bottom and the fides, is retarded; and therefore the fection muf, frombeeng thallow, become a little deeper, and the lurface will be convex for fome diftance till all comes intotrain. When this is efablifice, the filaments nearelt the bottom and fide are moving floweft, and the furface (in the middle efpecially) retains the greateft velocity, gliding over the reft. The velocity in the canal, and the depth of the fection, adjuft themfelves in fuch a manner that the difference between the furface of the bafon and the furface of the uniform fection of the caral correfponds exactly to the velocity. Thus, if this be obferved to be two feet in a fecond, the difference of height will be \(\frac{3}{x_{0}}\) ths of an inch.

All the practical quefions that are of confiderable importance refperting the motion of water in aqueciucis, may be eafily, though not elegantly, folved by means of the tables.

But it is to be remembered, that thefe tables relate only to uniform motion, that is, to water that is in train, and where the velocity fuffers no change by lengthenin? the conduit, provided the flope remain the fame. It is much more difficult to determine what vill be the velocity, \&c. in a caral of which nothing is given but the form, and llope, and depth of the entry, with ut faving how deep the water runs in it. And it is here that the common doctrines of hydraulics are moft in fault, and unable to teach us hov deep the water will run in a canal, though the depth of the bafon at the entry be perfectly known.- Retween the part of the canal which is in train and the bafon, there is an interval where the water is in a fate of acceleration, and is afterwards retarded.

The determination of the motions in this interval is exceedingly

Water*
warkfo

WaterWurks.
exceedingly difficult, even in a rectangular canal. It was one great aim of M. Buat's experiments to afcertain this by meafuring accurately the depth of the water. But he found that when the flope was but a very few inches in the whole length of his canal, it was not in train for want of greater length; and when the flope was fill lefs, the fmall fractions of an inch, by which he was to judge of the variations of depth, could not be meafured with fufficient accuracy. It would be a moft defirable point to determine the length of a canal, whofe flope and other dimenfions are given, which will bring it into train; and what is the ratio which will then obtain between the depth at the entry and the depth which will be maintained. Till this be done, the engineer cannot afcertain by a direct procels what quantity of water will be drawn off from a refervoir by a given canal. But as yet this is out of our reach. Experiments, however, are in view which will promote the invertigation.

But this and fimilar queftions are of fuch importance, that we cannot be faid to have improved hydraulics, unlefs we can give a tolerably precife anfwer. This we can do by a fort of retrograde procels, proceeding on the principles of uniform motion eftablifhed by the Chevalier Buat. We may fuppofe a train maintained in the canal, and then examine whether this train can be produced by any fall that is poffible at the entry. If it can, we may be certain that it is fo produced, and our problem is folved.

We thall now point out the methods of anfwering Come chief quefions of this kind. - Quefl. 1. Given the flope \(s\) and the breadth \(w\) of a canal, and the height H of the furface of the water in the bafon above the bnttom of the entry; to find the depth \(h\) and velocity \(V\) of the fream, and the quantity of water \(Q\) which is difcharged ?
N. The chief dificulty is to find the depth of the Aream where it is in train. For this end, we may fimplify the hydraulic theorem of uniform mation in \(\mathrm{N}^{\circ} 59\). of the article River; making \(V=\frac{\sqrt{N \rho d}}{\sqrt{S}}\), where \(g\) is the velacity (in inches) acquired in a fecond by falling, \(d\) is the hydraulic mean depth, and \(\sqrt{ } S\) ftands for \(\sqrt{S}-\mathrm{L} \sqrt{\mathrm{S}+1.6} \mathrm{~N}\) is a number to be fixed by experiment (fee River, \(\mathrm{N}^{0}\).53.) depending on the contraction or obifruction fultained at the entry of the canal, and it may in mof common cales be taken \(=244\); fo that \(\sqrt{\mathrm{Ng}}\) may be fomewhat lefs than 307. To find it, we may begin by taking for our depth of Aream a quantity \(h\), fomeshat fmaller than \(H\) the height of the furface of the bafon above the bottom of the canal. With this depth, and the known width \(w\) of the canal, we can find the hydraulic depth d (See Rivers, \(\mathrm{N}^{0} 48\) ). Then with \(\sqrt{ } d\) and the flope find V by the Table: make this \(\mathrm{V}=\frac{\sqrt{\mathrm{Ng} d}}{\sqrt{ } \mathrm{~S}}\). This gives \(\sqrt{\mathrm{Ng} g}=\frac{V \sqrt{ } S}{\sqrt{d}}\). This value of \(\mathrm{N} g\) is fufficiently exact ; for a fmall error of depth hardly affects the hydraulic mean depth.

After this preparation, the expreflion of the mean veLacity in the canal will be \(\frac{\sqrt{N g}-\sqrt{\frac{u h}{u+2 h}}}{\sqrt{S}}\) The
height which will produce this velocity is \(\frac{N g}{2 G S}\left(\frac{w \hbar}{w+2 h}\right)\).

\section*{Water
Morice} Now this is the flope at the entry of the canal which produces the velocity that is afterwards maintained againt the obftructions by the flope of the canal. It is therefore \(=\mathrm{H}-/\). Hence we deduce
\[
\begin{aligned}
& k=\frac{-\left(w\left(\frac{\mathrm{~N} g}{2 \mathrm{GS}}+1\right)-2 \mathrm{H}\right)}{4} \\
& +\frac{\sqrt{8 \mathrm{H} w+\left(w\left(\frac{\mathrm{Ng}}{2 \mathrm{GS}}+1\right)-2 \mathrm{H}\right)^{2}}}{4}
\end{aligned}
\]

If there be no contraction at the entry, \(g=G\) and \(\frac{9}{2 G}=\frac{1}{2}\).

Having thus obtairsed the depth \(\hbar\) of the fiream, we obtain the quantity of water by combining this with the width \(w\) and the velocity \(V\).

But as this was but an approximation, it is neceffary to examine whether the velocity V be poffible. This is very eafy. It muft be produced by the fall \(\mathrm{H}=h\). We fhall have no occafion for any correction of our firf affumption, if \(h\) has not been extravagantly erroneous, becaufe a fmall mittake in \(h\) produces almof the fame variation in \(d\). The teft of accuracy, however, is, that \(h\), together with the height which will produce the vélocity V, muft make up the whole height H. Affuming \(h\) too fmall, leaves \(\mathrm{H}-h\) too great, and will give a fmall velocity V , which requires a fmall value of \(\mathrm{H}-h\). The error of \(\mathrm{H}-h\) therefore is always greater than the error we have committed in our firf "aflumption. Therefore when this error of \(H-h\) is but a trifle, fuch as one-fourth of an inch, we may reft fatisfed with our anfwer.

Perhaps the eafielt procels may be the following: Suppofe the whole fream in train to have the depth \(\mathbf{H}\). The velocity V obtained for this depth and nlope by the Table sequires a certain productive height \(\boldsymbol{\psi}\). \({ }^{q}\) Make \(\sqrt{\mathrm{H}}+u: \mathrm{H}=\mathrm{H}: h\), and \(h\) will be exceedingly near the truth. The reafon is obvious.

Quef. 2. Given the difcharge (or quantity to be furnified in a fecond) \(Q\), the height \(H\) of the bafon above the bottom of the canal, and the llope; to find the dimenfions of the canal ?

Let \(x\) and \(y\) be the depth and mean width. It is plain that the equation \(\frac{Q}{x y}=\sqrt{2 G} \sqrt{H-x}\) wll give a value of \(y\) in terms of \(x\). Compare this with the value of \(y\) obtained from the equation \(\frac{Q}{x y}=\frac{\sqrt{N S}}{\sqrt{S}}\) \(\sqrt{\frac{x y}{y+2 x}}\). This will give an equation containing only 2 and known quantities. But it will be very complicated, and we muft have recourfe to an approximation. This will be beft undertood in the form of an example.

Suppofe the depth at the entry to be 8 inches, and the flope rovo. Let 1200 cubic feet of water per minute be the quantity of water to be drawn off, for working machinery or any other purpofe; and let the canal

\section*{W A T 「 657 ] W A T}

Watef- be fuppofed of the beft form, recommended in \(\mathrm{N}^{\circ} 69\). of the article Rivèr, where the bafe of the foping fide is four-thirds of the height.
I? The flightelt confideration will how us that if \(\frac{\mathrm{V}^{2}}{744}\) be taken for the height producing the velocity, it cannot exceed 3 inches, nor be lefs than 1 . Suppofe it \(=2\), and therefore the depth of the flream in the canal to be 16 inches; find the mean width of the canal by the equation \(w=\frac{Q}{h\left(1-0.1\left(\frac{307}{7}-0.3\right)\right.}\), in which \(Q\)
\[
h\left(\sqrt{d-0.1}\left(\frac{307}{\sqrt{3}}-0.3\right)\right.
\]
is 20 cubic fect (the 60th part of 1200 ), \(\sqrt{ } \mathrm{S}\) is \(=\) \(128.153,=\sqrt{1000}-L \sqrt{1000+1.6}\), and \(h=16\). This gives \(w=5.52\) feet. The fection \(n=7.36\) feet, and \(\overrightarrow{\mathrm{V}}=32.6\) inches. This requires a fall of 1.52 inches inftead of 3 inches. Take this from 18 , and there remains 16.48 , which we hall find not to differ onetenth of an inch from the exact dcpth which the water will acquire and maintain. We may therefore be fatisEed with affuming 5.36 feet as the mean width, and 3.53 feet for the width at the bottom.

This approximation proceeds on this confideration, that when the width diminithes by a fmall quantity, and in the fame proportion that the depth increafes, the hydraulic mean depth remains the fame, and therefore the velocity alfo remains, and the quantity difcharged changes in the exact proportion of the fection. Any minute error which may refult from this fuppofition, may be corrected by increafing the fall producing the velocity, in the proportion of the frit hydraulic mean depth to the mean depth correfponding to the new dimenfions found for the canal. It will now become 1.53, and V will be 32.72 , and the depth will be 16.47 . The quantity difcharged being divided by V , will give the fection \(=7.335\) feet, from which, and the new depth, we obtain 5.344 for the width.

This and the foregoing are the moft common queftions propofed to an engineer. We afferted with fome confidence that few of the profeffion are able to anfwer them with tolerable precifion. We cannot offend the profeffional gentlemen by this, when we inform them that the Academy of Sciences at Paris were occupied during feveral months with an examination of a plan propofed by M. Parcieux, for bringing the waters of the Yvette into Paris; and after the moft mature confideration, gave in a report of the quantity of water which M. De Parcieux's aqueduet would yield, and that their report has been found erroneous in the proportion of at leal 2 to 5: For the waters have been brought in, and exceed the report in this proportion. Indeed long after the giving in the report, M. Perronet, the moft celebrated engineer in France, affirmed that the dimenfions propofed were much greater than were neceffary, and faid that an aqueduct of \(5^{\frac{7}{2}}\) feet wide, and \(3^{\frac{T}{5}}\) deep with a flope of \(\overline{1} 5\) inches in a thoüfand fathoms, would have a velocity of 12 or 13 inches per fecond, which would bring in all the water furnifhed by the propoled fources. The great diminution of expence occafioned by the alteration encouraged the community to undertake the work. It was accordingly begun, and a part executed. The water was found to run with a velocity of near 19 inches when it was 3 y feet deep. M. Perronet founded his computation on VoL. XX. Part II.
lis own experience alone, acknowledging that he had no theory to inftruct him. The work, was carried no farther, it being foand that the city could be fupplied at a much fmaller expence by fteam engines erected by Boulton and Watt. But the facts which occurred in the partial execution of the aqueduct are very valuable. If M. Perronet's aqueduet be examined by our general
 which we deduce the velocity \(=18 \frac{2}{3}\), agreeing with the obfervation with attonifhing precifivn.

The experinents at 'lurin by Michaclotti on canale were very numerous, but complicated with many circumfances which would render the difculfion too long for this place. When cleared of thefe circumftances, which we have done with fcrupulous care, they are allo abundantly conformable to our theory of the uniform motion of running waters. But to return to our fubject :

Should it be required to bring off at once from the bafon a mill courle, having a determined velocity for driving an underlhot wheel, the problem becomes eafier, becaufe the velocity and flope combined determine the hydraulic mean deptly at once; and the depth of the Itream will be had by means of the height which mult be taken for the whole depth at the entry, in order to produce the required velocity.

In like manner, having given the quantity to be dif charged, and the velocity and the depth at the entry; we can find the other dimenfions of the channel ; and the mean depth being found, we can determine the flope.

When the nope of a canal is very fmall, fo that the depth of the uniform fream differs but a little from that at the entry, the quantity difcharged is but fmall. But a great velocity, requiring a great fall at the entry, produces a great diminution of depth, and therefore it may not compenfate for this diminution, and the quantity difcharged may be fmaller. Improbable as this may appear, it is not demonftrably falfe; and hence we may fee the propriety of the following

Quffion 3. Given the depth H at the entry of 2 rectangular canal, and alfo its width w; required the nlope, depth, and velocity which will produce the greateft poffible difcharge ?

Let \(x\) be the unknown depth of the flream. H-x is the productive fall, and the velocity is \(\sqrt{2 G}\) \(\sqrt{\mathrm{H}-x}\). This multiplied by \(w x\) will give the quantity difcharged. Therefore \(w x \sqrt{2 \mathrm{G}} \sqrt{\mathrm{H}-x}\) muft be made a maximum. The common prucefs for this will give the equation, \(2 \mathrm{H}=3 x\), or \(x=\frac{2}{3} \mathrm{H}\). The mean velocity will be \(\sqrt{2 \mathrm{G}}, \sqrt{\frac{3}{3} \mathrm{H}}\); the fection will be \(\frac{2}{3} w \mathrm{H}\), and the difcharge \(=\frac{2}{3} \sqrt{2 \mathrm{G}} w \mathrm{H} \sqrt{\frac{1}{3} \mathrm{H}}\), and \(d=\frac{\frac{2}{3} w \mathrm{H}}{w+\frac{4}{3} \mathrm{H}}\). With thefe data the flope is eafily had by the formula for uniform motion.

If the canal is of the trapezoidal form, the inveltigation is more troublefome, and requires the refolution of a cubic equation.

It may appear ftrange that increafing the flope of a canal bevond the quantity determined by this problem can diminith the quantity of water conveyed. But one of thefe two things muft happen; either the motion will not acquire uniformity in fuch a canal for want of 40
length,

Water-
work.

Water- length, or the difcharge muft diminith. Suppeing,
\(\underbrace{\text { worts. }}\) however, that it could augment, we can judge how far
this can go. Let us take the extreme cafe by making the canal vertical. In this cale it becomes a fimple weir or walieboard. Now the difcharge of a walteboard is \(\frac{2}{3} \sqrt{2 G} w\left(h^{\frac{3}{2}}-\left(\frac{1}{2} h\right)^{\frac{3}{2}}\right.\). The maximum determined by the preceding problem is to that of the walteboard of the fame dimenfions as \(\mathrm{H} \sqrt{\frac{\mathrm{H}}{3}}: \mathrm{H}^{\frac{3}{2}}-\) \(\left(\frac{1}{2} \mathrm{H}\right)^{\frac{3}{2}}\), or as \(\mathrm{H} \sqrt{\frac{1}{3} \mathrm{H}}: \mathrm{H} \sqrt{\mathrm{H}}-\frac{1}{2} \mathrm{H} \sqrt{\frac{3}{2} \mathrm{H}},=5773\) : 6465 , nearly \(=9: 10\).

Having given the dimenfions and flope of a canal, we can difoover the relation between its expenditure and the time; or we can tell hose much it will fink the furface of a pond in 24 hours, and the gradual progrefs of this effect ; and this might be made the fubject of a particular problem. But it is complicated and difficult. In cafes where this is an interelling object, we may folve the queftion with fufficient accuracy, by calculating the expenditure at the beginning, fuppofing the bafon kept full. Then from the known area of the pond, we can tell in what time this expenditure will fink an inch; do the fame on the fuppofition that the water is one-third lower, and that it is two-thirds lower (noticing the contaction of the furface of the pond occationed by this abftraction of its waters). Thus we flall obta, three rates of diminution, from which we can eafily deduce the defired relation between the expenditure and the time.

Aqueduets derived from a bafon or river are commonly furnifhed with a fiuice at the entry. This changes exceedingly the fate of things. The flope of the canal may be precifely fuch as will mainain the mean velocity of the water which pafles under the fluice: in which cafe the depth of the fream is equal to that of the naice, and the velocity is produced at once by the head of water above it. But if the flope is lefs than this, the velocity of the iffuing water is diminifhed, and the water muft rife in the canal. This muft chieck the efflux at the fluice, and the water will be as it were tagnant above what comes through below it. It is exeremely difficult to determine at what precife flope the water will begin to check the eflux. The contraction at the lower edge of the board hinders the water from attaining at once the whole depth which it acquires afterwards, when its velocity diminifhes by the obftructions. While the regorging which thefe obftructions occafon does not reach back to the fluice, the eflux is not affected by it.-Eren when it does reach to the fluice, there will be a lefs depth immediately behind it than farther down the canal, where it is in train; becaufe the frift moving water which is next the botom drags with it the regarged warer which lies on it : but the canal mutt be rapid to make this difference of depth feufible. In ordinary canals, with moderate flopes at d velocities, the velocity at the fluice may be lafely, taken as if it were that which correfponds to the difference of denths above and below the fluice, where both were in train.
t Let therefore II be the depth above the fluice, and \(h\) the depth in the canal. I et e lie the elevation of the Aluice above the fole, and let \(b\) be its breadih. The difcharge will be \(e b \sqrt{H-h} \sqrt{2 G}\) for the Auice, and
\(w h \frac{\sqrt{N g}}{\sqrt{s}} \sqrt{\frac{w h}{w+2 h}}\) for the canal. \(\because\) Thefe mult be the fame. This gives the equation \(e b \sqrt{H-h} \sqrt{2 G}\) \(=w h \frac{\sqrt{N g}}{\sqrt{s}} \sqrt{\frac{w h}{w+2 h}}\) containing the folution of all the quetlions which can be propoled. The only uncertainty is in the quancity \(G\), which exprefles the velocity competent to the paffage of the water through the onifice, circumflanced as it is, namely, fubjected to contraction. This may be regulated by a proper form given to the ently into this onifice. The contradion may be almof amihilated by making the mafonry of a cycloidal form on buth fides, and alfo at the loner edge of the 成位e-board, fo as to give the orifice a form refembling fig. 5. D, in the article Rivers. If the fluice is thin in the face of a bafon, the contraction will reduce 2 G to 296 . If the fluice be as wide as the canal, 2 G will be nearly 500.

Quefion 4. Given the head of water in the bafon \(H\), the breadth \(b\), and elevation \(e\) of the fluice, and the breadth \(w\) and flope \(s\) of the camal, to find the depth \(B\) of the ftream, the velocity, and the difcharge?

We muft (as in Quffion 2.) make a firlt fuppoftion for \(h\), in order to find the proper value of \(d\). Then the equation \(e b \sqrt{H-h} \sqrt{2 G}=w h \frac{\sqrt{N g}}{V s}\) gives \(h=\) \(\frac{\mathrm{G} r^{2} l^{2} s}{w^{2} N g d}+\sqrt{\frac{G c^{2} b^{2} s H}{w^{2}} \frac{\mathrm{~N} g d}{g d}\left(\frac{\mathrm{G} \rho^{2} b^{2} s}{w^{2} N g d}\right)^{2}}\). If this value thall differ confiderably fiom the one which we affumed in order to begin the computation, make ufe of it for obtaining a new value of \(d\), and repeat the operation. We lhall rarely be obliged to perform a third operation.

\section*{The following is of frequent ufe :}

शuefion 5. Given the dimenfions and the flope, with the velocity and difcharge of a river in its ordinary flate, required the atea or fection of the fluice which will raife the waters to a certain height, fill allowing the fame quantity of nater to pals through ? Such an operation may render the rivers navigable for frall crafe or rafis above the fluice.

The problem is reduced to the determination of the fize of orifice which will difcharge this water with a velocity competent to the height to which the river is to be raifed; only we muft take into confideration the relocity of the water above the fluice, conffdering it as produced by a fall which makes a part of the height productive of the whole velocity at the flucce. Thacrefore H , in our invelligation, muft confit of the height to which we mean to taife the waters, and the height which will produce the velocity witl which the waters approach the fluice: \(h\), or the depth of the ftream, is the ordinary depth of the river. Then (ufing the for. ner (ymbols) we have \(e b \frac{w l \sqrt{\mathrm{Ng}} \frac{d}{\sqrt{2 G s(H-h)}}}{}=\) \(\frac{Q}{\sqrt{2 G(I-\sqrt{h})}}\).

If the area of the fluce is known, and we would learn the heipht to which it will raife the river, we have \(\mathrm{H}-h=\frac{Q^{2}}{2 G e^{2} b^{2}}\) for the expreftion of the rife of the water.

Yiaty nupls, water above its ordinary level. But from this we muft takethe height which would. produce the velucity of the river; fo that if the fluice were as wide as the river, and were-raifed to the ordinary furface of the water,

\section*{\(0^{2}\)} \(\frac{7}{2 G c^{2} b^{2}}\), which expreffes the height that produces the relocity under the fluice, mufl be equal to the depth of the river, and \(\mathrm{H}-\mathrm{h}\) will be \(=0\).
'The performance of aqueduct drains is a very important thing, and merits our attention in this place. While the art of managing waters, and of conducting them fo as to anfiver our demands, renders us very important fervice by embellihing our habitations, or promoting our commercial intercourle, the art of draining creates as it were new riches, fertilizing tracts of bog or marll, which was not only ufelef's, but hurtful by its unwholcfome exhalations, and converting them into rich partures and gay meadows. A wild country, occupied by marlhes wnich are inaccethible to herds or llucks, and ferve only for the haunts of water-fowls, or the retreat of a few poor fihermen, when once it is freed from the waters in which it is drowned, opens its lap to reccive the molt precious feeds, is foun clothed in the richeft gart, gives life and abundance to numerous herds, and never fails to become the delight of the indutrious cultivator who has enfranchifed it, and is attached to it by the labour which it colt him. In return, it procures him aoundance, and fupplies hin with the means of daily augmenting its fertility. No fpecics of agriculture exhibits fuch long-continued and progreffive improvement. New families flock to the fot, and there multiply; and there nature leems the more eager to repay their labours, in proportion as the has been obliged, againt her will, to keep her treafures locked up for a longer time, chilled by the waters. The countries newly inhabited by the human race, as is a great part of America, efpecially to the foulhward, are fill covered 10 a great extent with manfies and lakes; and they would long remain in this condition, if population, daily making new advances, did not increafe indully, by multiplying the cultivating hands, at the fame time that it increafes their wants. The Author of this beatutiful world has at the beginning formed the great malfes of mountain, has fcooped out the dales and floping hills, has traced out the courfes, and even formed the beds of the rivers: but he has left to man the care of making his place of abode, and the ficld which mult feed him, dry and confortable. For this tain is not beyond his powers, as the others are. Nay, by having this given to him in charge, he is richly repaid for his labour by the very flate in which he finds thofe countries into which he penetrates for the firt time. Being covered with lakes and forefts, the juices of the foil are kept for him as it were in referve. The air, the burning heat of the fun, and the continual wathing of rains, would have combined to expend and diflipate their ve--getative powers, had the fields been expofed in the famc deyree to their action as the inhabited and cultivated countries, the moft fertile moulds of which are long fince lodged in the bottom of the ocean. All this would have been completely loft through the whole extent of "South America, had it not been protected by the forefts, which man muft cut down, by the rank berbage whicl he muft burn, and by the marn and bog which
he mult defroy by draining. Let not ungratcful man complain of this. It is his duty to take on hirndelf the taik of opening up treafures, preferved on purpule for him with fo mucl judgement and care. If he has ditcernment and fenfibility, he wilf even thank the \(\Lambda\) uthor of all good, who has thus hufbunded them for lis ule. He will co-operate with his beneficent views, and will be careful not to proceed by wantonly fnatching at prefent any partial good, and by picking out what is molt catily got at, regardlefs of him who is to come afterwards to uncover and extract the remaining riches of the ground. A wife adminittration of fuch a country will think it their duty to leave a jut thate of this inheritance to their defcendants, who are entitled to expect it as the laft legatees. National plans of cultivation thould be formed on this principle, that the tteps taken by the prefent cultivators for realizing part of the riches of the infant country flall not obftruct the works which will afterwards be neceffary for alfo obtaining the remainder. This is carefully attended to in Holland and in China. No man is allowed to conduct tle drains, by which he recovers a picce of marh, in fuch a way as to render it much more dillicult for a neighbour, or even for his own fucceffor, to drain another piece, although it may at prefent be quite inacceffible. There remains in the middle of the molt culivated countries many marthes, which indultry has not yet attempted to drain, and where the legiflature has not been at pains to pre. vent many little abufes which have produced elevations in the beds of rivers, and rendered the complete draining of fome fpots impoffisle. Adminiftration fhould attend to fuch things, becaufe their confiqatences are great. The fciences and arts, by which alone thefe difficult and collly jobs can be performed, hould be protected, encouraged, and cherihed. It is only from fcience that we can obtain pinciples to dired thefe arts. The problem of draining canals is one of the molt important, and yet has hardly ever occupied the attention of the hydralic fpeculatit. We apprehend that M. Buat's theory will throw great light on it; and regret that the very limited condition of our prefent work will hardiy afford roon for a flight asetch of what may be done on the fubject. We fhall, however, attenpt it by a general problem, which will involve moit of the chief circumflances which occur in works of that kind.

Quef. 6. Let the hollow ground 1 (fig. 2.) be inundated by rains or fprings, and have no outlet but the canal \(A B\), by which it difcharges its water into the neighbouring river \(\dot{B C D E}\), and that its furface is nearly on a level with that of the iver at B . It can only drain when the river finks in the droughts of fummer; and even if it could then drain completely, the nutidi marh would only be an infecting neighbour. It may be propofed to drain it by one or more canals; and it is required to determine their lengths and other dimenfons, fo as to produce the beft effeets?

It is evident that there are many circumfances to determine the choice, and many conditions to be attended to.

If the canals \(\triangle C, A D, A G\), are re'pectively equal to the portions \(\mathrm{BC}, \mathrm{BD}, \mathrm{BE}\), of the river, and have the fame nopes, they will have the fame difcharge; but they are not for this reafon equivalent. The long ca. nal \(A E\) may drain the marth completely; while the Miort

W゙aterwurks.,

Wreter-s wortay
one \(A C\) cmill only do it in part; becaufe the difference of level between \(A\) and \(C\) is but inconuderable. Alro the frefbes of the river may totally obftruct the operation of AC , while the canal AE cannot be hurt by them, E being fo much lower than C. Therefore the canal mult be carried fo far down the river, that no frefhes there fhall ever raife the waters in the canal fo high as to reduce the flope in the upper part of it to fuch a level that the current fhall not be fufficient to carry off the ordinary produce of water in the marth.

Still the problem is indeterminate, admitting many folutions. This requifite difcharge may be accomplifhed by a thort but wide canal, or by a longer and narrower. Let us firt fee what folution can be made, fo as to accomplith our purpofe in the moft economical manner, that is, by means of the fmalleft equation.-We thall give the folution in the form of an example.
Suppofe that the daily produce of rains and fprings raifes the water \(1 \frac{1}{2}\) inch on an area of a fquare league, which gives about 120,000 cubic fathons of water. Let the bottom of the bafon be three feet below the furface of the frethes in the river at \(B\) in winter. Alfo, that the flope of the river is 2 inches in 100 fathoms, or \(\frac{3}{30} \mathrm{~d}\) th, and that the canal is to be 6 feet deep.
The canal being fuppofed nearly parallel to the river, it mult be at leaft 1800 fathoms long before it can be admitted into the river, otherwife the bottom of the bog will be lower than the mouth of the canal; and even then a hundred or two more fathoms added to this will give it fo little nope, that an immenfe breadth will be neceflary to make the difcharge with fo fmall a velocity. On the other hand, if the flope of the canal be made equal to that of the river, an extravagant length will be neceffary-before its admiffion into the river, and many obitacles may then intervene. And even then it mutt have a breadth of 13 feet, as may eaflly be calculated by the general hydraulic theorem. By receding from each of thefe extremes, we thall diminith the expence of excavation. Therefore,
\(:\) Let \(x\) and \(y\) be the breadth and length, and \(k\) the depth \((6\) feet \()\), of the canal. Let \(q\) be the depth of the bog below the furface of the river, oppofite to the bafon, \(D\) the difcharge in a fecond, and \(\frac{I}{a}\) the flope of the river. We muft make \(\hbar x y\) a minimum, or \(x y+y x=0\).

The general formula gives the velocity
 would give \(x\) and \(y\); but the logarithmic term renders it very complicated. We may make ufe of the fimple form \(\mathrm{V}=\frac{\ddot{V} \overline{\mathrm{Ng}}}{\sqrt{S}}\), making \(\sqrt{\mathrm{Ng}}\) nearly 2 y \(b\). This will be fufficiently exact for all eales which do not deviate far from this, becsufe the velocities are \({ }^{p}\) very nearly in' the fubduplicate ratio of the glopes.

To introduce thefe data into the equation, recolled that \(V=\frac{D}{h x} d=\frac{h x}{x+2 / h}\). As to \(S\), recollcet that the canal being fuppofed of nearly equal length with the river, \(\frac{y}{a}\) will exprefs the whole difference of-height,
and \(\frac{y}{a}-9\) is the difference of height for the canal, This quantity being divided by y, gives the value of

\section*{Waterw} works: -ros
\(\frac{1}{5}=\frac{y}{a}-q\). Therefore the equation for the canal becomes \(\sqrt{\mathrm{Ng}} \sqrt{\frac{h x}{x+2 h}} \sqrt{\frac{y}{a}-q} \frac{y}{y}\) Hence we deduce \(y=\frac{\mathrm{N} g g h^{3} x^{3}}{\frac{\mathrm{~N} g h^{3} x^{3}}{a}-D^{3}(x+2 h)}\) and \(y=\frac{\frac{3 N g q h^{3} x^{2} x}{N g h^{3} x^{3}}}{a^{2}}-D^{2}(x+2 h)\)
 \(\left.-\underline{N g h^{3} x^{3}}-\mathrm{D}^{2}(x+2 h)\right)^{2}\) If we fubfitute thefe.
values in the equation \(y x+x y=0\), and reduce it, we obtain finally,
\[
\frac{\mathrm{N} g h^{3} x^{3}}{a D^{2}}-3^{x}=8 h
\]

If we refolve this equation by making \(\mathrm{N} g=(296)^{2}\), or 87616 inches \(; h=72, \frac{1}{a}=\frac{3}{300}\), and \(D=518400\), we obtain \(x=39^{2}\) inches, or 32 feet 8 inches, and \(\frac{D}{h x^{2}}\), or \(\mathrm{V}=18,36\) inches. Now putting thefe values in the exact formula for the velocity, we obtain the flope of the canal, which is ry\% \({ }^{\frac{1}{6} 64}\), nearly 0,62 , inches in 100 fathorns.

Let \(/\) be the length of the canal in fathoms. As the river has 2 inches fall in 100 fathoms, the whole fall is \(\frac{21}{100}\) and that of the canal is \(\frac{0,62!}{100}\). The difference of thefe two mult be 3 feet, which is the difference between \({ }^{1}\) the river and the entry of the canal.. We have there. fore \(\left(\frac{2-0.62}{100}\right) l=36\) inches. Hence \(l=2604\) fathoms; and this multiplied by the fection of the canal gives 14177 cubic fathoms of earth to be removed.

This may furely be done, in moft cafes, for eight thillings each cubic fathom, which does not amount to 60001 . a very moderate. fum for completely draining of nine, fquare miles of country.

In order to judge of the importance of this problem, we have added two other eanals, one longer and the other floorter, having their widths and flopes fo adjufted as to enfure the fame performance.
\begin{tabular}{|c|c|c|c|c|}
\hline \multicolumn{5}{|l|}{\multirow[t]{2}{*}{-Width. - Velocity,}} \\
\hline \multicolumn{5}{|l|}{\multirow[b]{2}{*}{\(42 \quad 14.28\) тв \({ }^{\frac{1}{7} 88}\)}} \\
\hline & & & & \\
\hline -) 32 & 18.36 & \({ }^{\frac{1}{1}}\) & 2604 & 14177 \\
\hline 21 & 28.57 & & \(73^{81}\) & 25833 \\
\hline
\end{tabular}

We have confidered this important problem in its moft firmple ftate. If the bafon is far from the river, fo that the drains are not nearly parallel to it, and therefore have lefs flope attainable in their courfe, it is more difficult. \({ }^{0 y}\) Perhaps the beft method is to try two very éxtreme cafes and a middle one, and then a fourth, nearer to that extreme which differs leaft from the findule one in

\section*{W A T}
the quantity of excavation. This will point out on whien fide the minmum of excavation lies, and allo the haw by which it ju duinifhes and afterwards increafes: Then draw a line, on which fet off from one end the lengths of the cauals. At each length erect an ordenate reprefenting the excavation ; and draw a regular curve through the extremities of the ordinates. . From that point of the curve which is neareft to the bafe line, draw another ordinate to the bafe. This will point out the beft length of the canal with fufficient accuracy. The length will determine the flope, and this will give the width, by mèans of the general theorem. N.B. Thefe draining canals muft always come off from the bafon with evafated entries. This will prevent the lofs of much fall at the entry.

Two canals may fometimes be neceflary. In this cale expence may frequently be faved, by making one canal flow into the other. This, however, muft be at fuch a diftance from the bafon, that the fwell produced in the other by this addition may not reach back to the immediate neighbourhood of the bafon, otherwife it would impede the performance of both. For this purpofe, recourfe muft be had to Problem III. in \(\mathrm{N}^{\circ}\) 104. of the article River. We mult here obferve, that in this refpect canals differ exceedingly from rivers; rivers enlarge their beds,' fo as always to convey every increafe of waters; but a canal may be gorged through its whole length, and will then greatly diminih its difcharge. In order that the lower extremity of a canal may convey the waters of an equal canal admitted into it, their junction muft be fo far from the bafon, that the fivell occafioned by raifing its waters nearly \(\frac{x}{2}\) more (viz. in the fubduplicate ratio of 1 to 2 ) may not reach back to the bafon.

This obfervation points out another method of economy. Inftead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper diftance from the bafon. But the lower extremity will now be too fhallow to convey the waters of both. Therefore raife its banks by ufing the earth taken from its bed, which muft at any rate be difpofed of. Thus the waters will be conveyed, and the expence, eveni of the lower part of the long canal, will fcarcely be increafed.

Thefe obfervations muft fuffice for an account of the management of open canals; and we proceed to the confideration of the conduct of water in pipes.
"This is much more fimple and regular, and the general theorem requires very trifing modifications for adapting it to the cafe's or queftions that occur in the pratice of the civil engineer. Pipes are always made round, and therefore \(d\) is always \(\frac{1}{4}\) th of the diameter. The velocity of water in a pipe which is in train, is \(=\mathrm{V},=\frac{307(\sqrt{ } d-0,1)}{\sqrt{ }-\mathrm{L} \sqrt{ }+1, b_{z-s}}-\rho_{r}\left(\sqrt{ } d^{2}-2,\right)\) or \(=(\sqrt{\prime} d\) \(\div 0,1)\left(\frac{307}{\sqrt{s-L} \sqrt{s+1,6}}-0,3\right)\).

The chief queftions are the following:
Quefis I. Given the height \(H\) of the refervoir above the place of delivery and the diameter and length of the pipe to find the quapitity of yater difcharged in a fecond

Let \(L\) be the length, and \(h\) the fall which would pro. duce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obftructions. This may be expreffed in terms of the velocity by \(\frac{V^{2}}{2 G^{3}}\), \(G\) denoting the acceleration of gravity, correfponding to the manner of entry. When no methods' are adopted for facilitating the entry of the water, by a bell-fhaped funnel or otherwife, 2 G may be affumed as \(=500\) inches, or 42 feet, according as we meafure the velocity in inches or feet. The nope is \(\frac{1}{s^{3}}=\) \(\frac{\mathrm{H}-\frac{V^{2}}{2 \mathrm{G}}}{\mathrm{L}}\), which mufl be put into the general formula. This would make it very complicated. We may fimplify it by the confideration that the velocity is very fmall in comparifon of that arifing from the height H : confequently \(h\) is very frall. Alfo, in the fame pipe, the refiftances are nearly in the duplicate ratio of the velocities when thefe are fmall, and when they differ little among themfelves. Therefore make \(b=\frac{\mathrm{L}}{\mathrm{L}}\), taking \(h\) by guefs, a very little lefs than H. Then compute the mean velocity \(v\) correfponding to thefe data, or take it from the table. If \(h+\frac{v^{2}}{2 G}\) be \(=H\); we have found the mean velocity \(\mathrm{V}=\%\). If not, make the following proportion :
\(h: \frac{v^{2}}{2 \mathrm{G}}=\mathrm{H}-\frac{\mathrm{V}^{2}}{2 \mathrm{G}}: \frac{\mathrm{V}^{3}}{2 \mathrm{G}}\), which is the fame with this, \(h+\frac{v^{2}}{2 \mathrm{G}}: v^{2}=\mathrm{H}: \mathrm{V}^{2}\), and \(\mathrm{V}^{2}\) is \(=\frac{v^{2} \mathrm{H}}{h+\frac{v^{2}}{2 \mathrm{G}}}\)
\(=\frac{\frac{v^{2} \mathrm{H}}{2 \mathrm{G} h}+v^{2}}{2 \mathrm{G}},=\frac{v^{2} \cdot 2 \mathrm{GH}}{v^{2}+2 \mathrm{G} h}\).
If the pipe has any bendings, they muft be calculated for in the manner mentioned in the article RIver, \(\mathrm{N}^{\circ}\) 101 ; and the head of water neceffary for overcoming this additional refiftance being called \(\frac{\mathrm{V}^{3}}{\mathrm{~m}}\), the laft proportion muft be changed for
\[
h+v^{v}\left(\frac{1}{2 G}+\frac{1}{m}\right): v^{2}=H: V
\]

2uef.2. Given the height of the refervoir, the length of the pipe, and the quantity of water which is to be drawn off in a fecond; to find the diameter of the pipe which will draw it off?

Let \(d\) be confidered as \(=\frac{\text { th }}{}\) of the diameter, and let 1he reprefent the ratio of the diameter of a circle to its circumference. The fection of the pipe is \(4^{c} \dot{d}^{3}\). Let the guantity of water per fecond be \(Q ;\) then \(\frac{Q}{4 c d^{2}}\) is the mean velocity, Divide the length of the pipe by the height of the fefervoir above the place of delivery, "diminihed by a very fmall quaritity, and call the quouent S. Confider this as the flope of the conduit; the general formula now becomes to whotut pa: ic is 18s odt \(\frac{Q}{4^{2}}=\frac{307(\sqrt{ } d-0.1)}{\sqrt{d}-L \sqrt{ } \sqrt{s+1,06}}-0,3,\left(v\left(d \frac{1}{n} 0,1\right) \frac{0}{0}\right.\) \(\frac{Q}{4^{6} d^{2}}\)

Water. works:
chokes the pipes by dodging in their, upper parts, This is fometimes taken in along with the uater at the refervoir, when the entry of the pipe is too, near the-fur. face. This hould be caretully avoided, and it colts no trouble to do fo. If the entry of, the pipe is wo feet under the furface, no air can ever get in. Floats flould be placed above the entries, having. lids hinging from them, which will hlut the pipe before the water runs too low,

But air is alfo difengaged from rpring-water by mere. ly palling along the pipe. When pipes are fupplied by an engine, air is very ofter drawn in by the pumps in a difengaged ftate. It is alfo difengaged from its itate of chemical union, when the pumps have a luction-pipe of 10 or 12 feet, which is very common. In whatever way it is introduced, it collects in all the upper part of bendings, and chokes the paffage, fo that tometiroes not a drop of water is delivered. Our cocks flould be placed there, which thould be opened frequently by perfons who have this in charge. Defaguliers deferibes a contrivance to be placed on all fuch eminences, which does this of itfelf. It is a pipe with a cock, terminating in a finall ciftern. The key of the cock has a hollow ball of copper at the end of a lever. When there is no air in the main pipe, water comes out by this dif. charger, fills the ciftern, raifes the ball, and thus nluts the cock. But when the bend of the main contains air, it rifes into the cillern, and occupies the upper part of it. Thus the floating ball falls down, the cock opens and lets out the air, and the ciftern again filling with water, the ball rifes, and.the cock is again fhut.

A very neat contrivance for this purpofe was invented by the late Profeffor Ruffel of Edinburgh. The cy. lindrical pipe BCDE (fig. 3.), at the upper end of a bending of the nain, is icrewed on, the upper end of which is a flat plate perforated with a faall hole \(\mathcal{F}\). This pipe contains a hollow copper cylinder. \(G\), to the upper part of which is faflened a piece of foft leather H. When there is air in the pipe, it comes out by the tole \(A\), and occupies the difcharger, and then efcapes throngh the hole F. The water fullows, and, rifing in the difcharger, lifts up the , hollow cylinder G, caufing the leather \(H\) to apply itfelf to the plate CD, and thut the hole. Thus the air is difcharged without the fma!]eft lofs of water.

It is of the molt material confequence that there be no contraction in any part of a conduit. This is evident ; but it is alfo prudent to avoid all unneceffary enlargements. For when the conduit is full of water moving along it, the velocity in every fection is inverfeIy proportional to the area of the fection : it is therefore diminifhed wherever the pipe is enlarged; but it muft again be increafed where the pipe contrate. This cannot be without expending force in the acceleration. This confumes part of the impelling power, whether this be a head of water, or the force of an enginc. See what is faid on this fubject in the article Pumps, \(\mathrm{N}^{0} 8_{3}\), \&cc. Nolhing is gained by any enlargement; and every contraction, by requiring an augmentationof velocity, employs a part of the impelling force precifely equal to the weight of a column of water whofe bafe is the contracted paffage, and whole height is the fall which would produce a velocity equal to this augmentation. This point feems to have been quite overlooked by engineers of the firf eminence, and has in many infances
greatly

\section*{W A T [ 663 ] W A T}
greatly diminilhed the performance of their beft works. It is no lefs detrimental in open canals; becaufe at every contrection a lmall fall is required for reftoring the relocity lof in the enlargement of the ramal, ty which the general flope and velacity are dimmilherl. Another pont which mull be attended to in the cundueting of water is, that the motion finuid not be lubfulory, but continuons. When the water is to be driven along a man by the trokes of a reciprocacing engine, it hould we forced into an air-box, the fpring of which may preferve it in mution alous the whole fublequent main. If the water is brought to redl at cvery lacceflive llroke of the pifton, the whole mafs mult again be put in motion through the whole length of the main. This requires the fame ufelels expenditure of pover as to communicate this motion to as much dead matter; and this is oucr and above the force which may be neceffary for raifing the water to a certain height; which is the only cincumftance that enters into the calculation of the power of the pamp-enginc.

An air-box removes this imperfection, becaufe it keeps up the motion during the retuming troke of the pifton. The compreftion of the air by the active flruke of the pifton mult be fuch as to continue the impulfe in oppofition to the contrary preflure of the water (if it is to be raifed to fome height), and in oppofition to the friction or other reffances which arife from the motion that the water really acquires. Indeed a very confiderable force is empluyed here allo in changing the mution of the water, which is forced out of the capaciuss airbox into the narrow pipe; and when this change of motion is not judicioully managed, the expenditure of power may be as great as if all were brought to reft and again put into motion. It may even be greater, by caufing the water to move in the oppofite direction to its former motion. Of fuch confequence is it to have sll thefe circumitances fcientifically confidered. It is in fuch particulars, unheeded by the ordinary herd of engineers or pump-makers, that the fuperiority of an intelligent practitioner is to be feen.

Another material point in the conduet of water in pipes is the difribution of it to the different perfons who have occafion for it. This is rately done from the rifing main. It is ufual to fend the whole into a ciftern, from which it is afterwards conducted to different places in feparate pipes. Till the difcovery of the general theorem by the chevalier Buat, this has been done with great inaccuracy: Engineers think that the different purchafers from water-works receive in proportion to their refpective bargains when they give them pipes whofe areas are proportional to thefe payments. But we now fee, that when thele pipes are of any confiderable length, the waters of a larger pipe run with a greater velocity than thofe of a fmaller pipe having the fame flope. A pipe of two inches diameter will give much more water than four pipes of one inch diameter; it will give as much as five and a half fuch pipes, or more; becaufe the fquares of the difcharges are very nearly as the fifth powers of the diameters. This poimt cught therefore to be carefully confidered in the bargains made with the proprietors of water-works, and the payments made in this proportion. Pernaps the molt unexceptionable methed would be to make a d uble diftribution Let the wafer be frnt let off in its p:oper proportions into a fecond feries of frall cilterns, -.914
and let cach lave a pipe which will convey the whole water that is difcharged into it. The firt diftribution nay be made encircly by pipes of one inch in diameter; this would leave nothing to the calculation of the diltributor, for every man would pay in proportion to the number of fuch pipes which run into his own ciftern.

In many cafes, however, water is difributcd by pipes derived from a main. And lere another circumblance comes into action. When water is paffing along a pipe, its preflure on the fides of the pipe is diminifted by its volocity; and if a pipe is now derived frum it, the quantity drawn off is alfo dimmined in the fubdualicate ratio of the preffures. It the preflure is reduced to one faurth, one-ninth, one-fixteenth, \&c. the dilcharge from the lateral pipe is reduced to one-half, one-thitd, one-fourth, \&ic.

It is therefore of great importance to determine, what this diminution of preffure is which ariles from the motion alung the main.

It is plain, that if the water fuffered no reflance in the main, its velocity would be that with which it entered, and it would pals along without exertisig any preffure. It the pipe were flut at the end, the preffure on the fides would be the full prefluse of the head of water. If the head of water remain the fame, and the end of the tube be contracted, but not ftopped entirely, the velocity in the pipe is diminillied. If we would have the velocity in the pipe with this contracted mouth augmented to what it was before the contraction was made, we mult employ the preffure of a piftun, or of a head of water. This is propagated through the fluid, and thus a preffure is immediately cxcited on the fides of the pipe. New obftructions of any kind, arifing from friction or any other caufe, produce a diminution of velucity in the pipe. But when the natural velocity is checked, the particles react on what obftructs their motion; and this action is uniformly propagated through a perfect fluid in every direction. The refiltance therefore which we thus afcribc to friction, produces the fame lateral preffure, which a contraction of the orifice, which equally diminithes the velocity in the pipe, would do. Indeed this is demonftrable from any diflinct notions that we can form of thefe obfructions. They proceed from the want of perfect fmoothnefs, which obliges the particles next the fides to move in undulated lines. 'This cxcites tranfverfe forces in the fame manner as any conftrained curvilineal motion. A particle in its undulated path tends'to efcape from it, and acts on the lateral particles in the fame manner that it would do if moving fingly in a capillary tube having the fame undulations; it would prefs on the concave fide of every fuch undulation. Thus a preffure is ex. erted among the particles, which is propagated to the fides of the pipe; or the diminution of velocity may arife from a vifcidity or want of perfect tlaidity. This obliges the particle immediately preffed to drag along with it another particle which is withbeld by adhefion to the fides. This requires additional preffure from a mifton, or an additional head of water; and this preffure alfo is propagated to the fides of the pipe.

Hence it Thould follow, that the preffure which water in motion exerts on the fides of its conduit is equal to that which is compelent to the lead of water whichs
impels

Wiaterv:orks.

Water. works.
impels it into the pipe, diminifhed by the head of water competent to the actual velocity with which it moves along the pipe. Let \(H\) reprefent the head of water which impels it into the entry of the pipe, and \(h\) the head which would produce the actual velocity; then \(\mathrm{H}-h\) is the column which would produce the preflure exerted on its fides.

This is abundantly verified by very fimple experiments. Let an upright pipe be inferted into the fide of the main pipe. When the water runs out by the mouth of the main, it will rife in this branch till the weight of the column balances the preflure that fupports it; and if we then afcertain the velocity of the iffuing water by means of the quantity difcharged, and compute the lead or height neceffary for producing this velocity, and fubtract this from the height of water above the entry of the main, we ftrall find the height in the branch precifely equal to their difference. Our readers may fee this by examining the experiments related by Gravefande, and fill better by confulting the experisoents narrated by Boffut, \(\oint 558\), which are detailed with great minutenefs; the refults correfponded accurately with this propofition. The experiments indeed were not heights of water fupported by this preffure, but water expelled by it through the fame orifice. Indeed the truth of the propofition appears in every way we can confider the motion of water. And as it is of the firf importance in the practice of conducting water (for reafons which will prefently appear), it merits a particular attention. When an inclined tube is in train, the accelerating power of the water (or its weight diminifhed in the proportion of the length of the oblique column to its rertical height, or its weight multiplied by the fraction \(\frac{1}{s}\), which expreffes the flope), is in equilibrio with the obitructions; and therefore it exerts no preffure on the pipe but what arifes from its weight alone. Any part of it would continue to flide down the inclined plane with a conitant velocity, though detached from what follows it. It therefore derives no preffure from the head of water which impelled it into the pipe. The fame muft be faid of a horizontal pipe infinitely fmooth, or oppofing no refiftance. The water would move in this pipe with the full velocity due to the head of water which impels it into the entry. But when the pipe oppofes an obitruction, the head of water is greater than that which would impel it into the pipe with the velocity that it actually has in it ; and this additional preflure is propagated along the pipe, where it is balanced by the actual refiftance, and therefore excites a quaqua verfum preffure on the pipe. In thort, whatever part of the head of water in the refervoir, or of the preflure which impels it along the tube, is not employed in producing velocity, is employed in acting againft fome obftruction, and excites (by the reaction of this obftruction) an equal preffure on the tube. The rule therefore is general, but is fubject to fome modifications which deferve our altention.
rig. 4.
In the fimply inclined pipe BC (fig. 4.), the preffure on any point \(S\) is equal to that of the head \(A B\) of water which impels the water into the pipe, wanting or minus that of the head of water which would communicate to it the velocity with which it actually moves. This we thall call \(x\), and confider it as the weight of a colomn
of water whofe length allo is \(x\). In like manner \(H\) may be the column \(A B\), which impels the water into the pipe, and would communicate a certain velocity; and \(/ 4\) may reprefent the column which would communicate the actual velocity. We have therefore \(x=\) H—h.

In the pipe HIKL, the preffure at the point I is AH \(-h-\mathrm{IO},=\mathrm{H}-h-1 \mathrm{O}\); and the preflure at K is H \(h+P K\).

And in the pipe DEFG, the prefure on \(E\) is \(=A R\) \(-h-\mathrm{FM},=\mathrm{H}-h-\mathrm{EM}\); and the preffure at \(\overline{\mathrm{F}}\) is H \(-h+\mathrm{FN}\).

We mult carefully diftinguith this preffure on any fquare inch of the pipe from the obitruction or refiftance which that inch actually exerts, and which is part of the caule of this preffure. The preflure is (by the laws of hydroftatics) the fame with that exerted on the water by a fquare inch of the pifton or forcing head of water. This mult balance the united obftructions of the whole pipe, in as far as they are not balanced by the relative weight of the water in an eaclofed pipe. Whatever be the inclination of a pipe, and the velocity of the water in it, there is a certain part of this refiftance which may not be balanced by the tendency which the water has to flide along it, provided the pipe be long enough; or if the pipe is too fhort, the tendency down the pipe may more than balance all the refiftances that obtain below. In the firft cafe, this overplus mutt be balanced by an additional head of water; and in the latter cafe the pipe is not in train, and the water will accelerate. There is fomething in the mechanifm of thefe motions which makes a certain length of pipe neceffary for bringing it into train; a certain portion of the furface which acts in concert in obftructing the motion. We do not completely underftand this circumftance, but we can form a pretty diftinct notion of its mode of acting. The film of water contiguous to the pipe is withheld by the obAfruction, but glides along; the film immediately within this is withheld by the outer film, but glides through it: and thus all the concentric films glide within thofe around them, fomewhat like the fliding tubes of a fpy glafs, when we draw it out by taking hold of the end of the innermoft. Thus the fecond film pafies beyond the firf or outermoft, and becomes the outermoft, and rubs along the tube. The third does the fame in its turn; and thus the central filaments come at laft to the outfide, and all fuftam their greateft poffible obftruction. When this is accomplifhed, the pipe is in train. This requires a certain length, which we cannot determine by theory. We fee, however, that pipes of greater diameter muft require a greater length, and this in a proportion which is probably that of the number of filaments, or the fquare of the diameter. Buat found this fuppofition agree well enough with his experiments. A pipe of one inch in diameter futtained no change of velocity by gradually fhortening it till he reduced it to fis: feet, and then it difcharged a little more water. A pipe of two inches diameter gave a fenfible augmentation of velocity when fhortened to 25 feet. He therefore fays, that the fquare of the diameter in inches, multiplied by 72 , will exprefs (in inches) the length heceflary for putting any pipe in train.

The refiftance exerted by a fquare inch of the pipe makes but a fmall part of the preffure which the whole
refifances

\section*{W A T [ 605 ] W A T}

Wher- refifances occafion to be exerted there befure they can : vorks. syorks. be overcome. The refiftance may be reprefented by \(\frac{d}{s}\) ? when \(d\) is the hydraulic depth (one-fourth of the diameter), and \(s\) the length of a column whofe vertical height is one inch, and it is the relative weight of a column of water whofe bale is a fquare inch, and height is \(d\). For the refitance of any length s of pipe which is in train, is equal to the tendency of the water to flide down (being balanced by it); that is, is equal to the weight of this column multiplied by \(\frac{1}{5^{\circ}}\). The magni-
tude of this column is had by meltiplying its length by its fection. The fection is the product of the border \(h\) or circumference, multiplied by the mean depth \(d\), or it is \(b d\). This multiplied by the length, is \(b d s\); and this multiplied by the flope \(\frac{1}{5}\) is \(b d\), the relative weight of the column whofe length is \(s\). The relative weight of one inch is therefore \(\frac{b d}{s}\); and this is in equilibrio with the refiftance of a ring of the pipe one inch broad. This, when unfolded, is a parallelogram \(b\) inches in length. One inch of this therefore is \(\frac{d}{s}\), the relative weight of a column of water liaving \(d\) for its beight and a fquare inch for its bafe. Suppofe the pipe four inches in diameter, and the flope \(=253\), the refiftance is one grain; for an inch of water weighs 253 grains.
This knowledge of the preflure of water in motion is of great importance. In the management of rivers and canals it inftruets us concerning the damares which they produce in their beds by tearing up the foil ; it informs us of the ftrength whicls we muft give to the banks: but it is of more confequence in the management of clofe conduits. By this we muft regulate the ftrength of our pipes; by this alfo we mufl afeertain the quantities of water which may be drawn of by lateral branches from any main conduit:
With refped to the firft of thefe objects, where fecurity is our fole concern, it is proper to confider thie prefiure in the molt unfavourable circumfances, viz. when the end of the main is gut. This cafe is not unfrequeni. Nay, when the water is in motion, its velocity in a conduit feldom exceeds a very few feet in a fecond. Eight fect per fecond requires only' one 'foot of water to produce it. We fhould therefore eflimate the ftrain on all conduits by the whole height of the refervoir.

In order to adjuf the ftrength of a pipe to the ftrain, we may conceive it as confilting of two half cylinders of infuperable ffrength, joined along the two feems, where the Arength is the fame with the ordinary frength of the materials of which it is made. The infide preflure tends to burlt the pipe by tearing open thefe feams; and each of thefe two feams is equal to the weight of a column of water whofe height is the depth of the feam below the furface of the refervoir, and whofe bafe is an inch hroad and a dianeter of the pipe in length. This follows from the common principles of hydroftatics.
Suppofe the pipe to be of lead, one foot in diameter and \(r 00\) feet under the furface of the refervoir. Water

Voz. XX. Part II.
weighs \(62_{2}^{3}\) pounds per foot. The bafe of our colurema is therefore 'isth of a foot, and the tendency to burt the pipe is \(100 \times 62 \frac{1}{2} \times{ }^{1}\) th \(={ }^{6} \frac{23}{2}{ }^{\circ},=521\) pounds nearly. Therefore an inch of one feam is ttraitred by \(260 \cdot \frac{5}{2}\) pounds. A rod of lead one inch fquare is pulled afunder by 860 pounds (fee STHENGTH of Materiale, \(\mathrm{N}^{\circ} 4^{0}\).). Therefore, if the thicknefs of the fcam is \(=\frac{20}{8} \frac{0}{6}\) inches, or one-third of an inch, it will juft with. ftand this ftrain. But we muft make it much ftronger than this, efpecially if the pipe leads from an cogine which fends the water along it by flarts. Belidor and Defaguliers have given tables of the thicknels and weights of pipes which experience has found fufficient for the different materials and depths. Defaguliers fays, that a leaden pipe of three-fourtho of an inch in thicknefs is flrong enough for a height of 140 feet and diameter of feren inches. Fiom this we may calculate all others. Belidor fays, that a leaden pipe 12 inches diameter and 60 feet deep floould be half an inch tlick: but thefe things will be more properly computed by means of the lift given in \(\mathrm{N}^{\circ} 40\) of the article Strenc Tir of Materials.

The application which we are moft ansious to make of the knowledge of the preffure of moving waters is the derivation from a main conduit by lateral branches. This occurs very frequently in the difltibution of waters among the inhabitants of towns; and it is fo imperfectly underfoad by the greateft past of thofe who take the name of engineers, that individuals have no fe-: curity that they fhall get even one half of the water they bargain and pay for; yet this may be as accurately afcertained as any other problem in hydraulics by means of our general theorem. The cafe therefore merits our particular attention.
It appears to be determined already, when we have afcertained the preflures by which the water is impelled into thefe lateral pipes, efpecially after we have faid that the experiments of Boflut on the actual difcharges from a lateral pipe fully confirm the theoretical doctrine. But much remains to be confidered. We have feen that there is a wall difference between the difcharge made through a hole, or even through a thort pipe, and the difcharge from the far end of a pipe derived from a main conduit. And even when this has been afcertained by our new theory, the difcharge thus modified will be found confiderably different from the real ftate of things : For when watcr is flowing along a main with a known velocity, and therefore exerting a known preffure on the circle which we propofe for the entry of a branch, if we infert a branch there water will go along it: but this will generally make a confiderable change in the motion along the maiv, and therefore in the preffure which is to expel the water. It alfo makes a confiderable change in the whole quantity which paffes along the antetior part of the main, and a fill greater change on what moves along that part of it which lies beyond the brancly: it therefore affects the -quantity neceflary for the whole fupply, the force that is required for propelling it, and the quantity delivered by other branches, . This part therefore of the management of water in conduits is of confiderable importance and intricacy. We can propofe in this place nothing more than a folution of fuch leading queftions as involve the chief circumftances, recommending to our readers the perufal of original works on this fubject. M. Boffut's

\section*{W A T [ 660 ] W A 汭}

Waterworks.
experiments are fully competent to the eftablifmment of the fundament principle. The hole through which the lateral difcharges were made was but a. few feet from the refervoir. The pipe was fucceffively lengthened, by whicin the refiflances were increafed, and the velocity diminithed. Put this did not affect the lateral difcharges, except by affecting the preflures; and the difcharges from the end of the main were fuppofed to be the fame as when the lateral pipe was not inferted. Although this was not ftrietly true, the difference was infenfible, becaufe the lateral pipe had but about the 18 th part of the area of the main.

Suppofe that the difcharge from the refervoir remains the fame after the oerivation of this branch, then the motion of the water all the way to the infertion of the branch is the fame as before; but, beyond this, the difcharge is diminifhed by all that is difcharged by the branch, with the head \(x\) equivalent to the preffure on the fide. The difcharge by the lower end of the main being diminifhed, the velocity and refflance in it are alfo diminithed. Therefore the difference between \(x\) and the head employed to overcome the friction in this fecond cafe, would be a needlefs or inefficient part of the whole load at the entry, which is impoffible; for every force produces an effect, or it is deftroyed by fome reaction. The effect of the forcing head of water is to produce the greateft difcharge correfponding to the obitructions; and thus the difcharge from the refervoir, or the fupply to the main, mult be augmented by the infertion of the branch, if the forcing head of water remains the fame. A greater portion therefore of the forcing head was employed in producing a greater difcharge at the entry of the main, and the remainder, lefs than \(x\), produced the preffure on the fides. This head was the one competent to the obltructions refulting from the velocity beyond the infertion of the branch; and this velocity, diminifhed by the difcharge already made, was lefs than that at the entry, and even than that of the main withont a branch. This will appear more diftinctly by putting the cafe into the form of an equation. Therefore let \(\mathrm{H}-x\) be the height due to the velocity at the entry, of which the effect obtains only horizontally. The head :s is the only one which acts on the fides of the tube, tending to produce the difcharge by the branch, at the fame time that it muft ovetcome the obftructions beyond the branch. If the oiifice did not exift, and if the force producing the velocity on a fhort tube be reprefented by \(2 G\), and the fection of the main be \(A\), the fupply at the entry of the main would be \(A \sqrt{2 \mathrm{G}} \sqrt{\mathrm{H}-\mathrm{B}}\); and if the orifice had no influence on the value of \(x\), the difcharge by the orifice would be \(\mathrm{D} \sqrt{\frac{x}{\mathrm{H}}}, \mathrm{D}\) being its difcharge by means of the head \(\mathrm{H}_{\text {, when }}\), the end of the main is thut; for the difcharges are in the fubduplicate ratio of the heads of water by which they are expelled; and therefore \(\sqrt{ } \mathrm{H}: \sqrt{x}=\mathrm{D}: \mathrm{D}: \sqrt{\frac{x}{\mathrm{H}}}(=\delta)\). But we have feen that \(x\) muft diminifh; and we know that the obftructhons are nearly as the fquaie roots of the velocilies, when the fe do not differ much among themfelves. Hherefore calling \(y\) " the preffure ar head which balances the refiftances of the main without a bsanch, while or
is the head neceflary for the main with abranch, w may inflitute this proportion, \(y: \mathrm{H}-y=x \cdot \frac{x(\mathrm{H}-y)}{y}\); and this 4 th term will exprefs the head producing the velocity in the main beyond the branch (as \(\mathrm{H}-y\) would have done in a main without a branch). This velocity bejond the branch will be \(\sqrt{2 \mathrm{G}} \sqrt{\frac{x(H-y)}{y}}\), and the difcharge at the end will be \(A \sqrt{2 G} \sqrt{\frac{y}{x(H-y)}}\). If to this we add the difcharge of the branch, the furn will be the whole difcharge, and therefore the whote fupply. Therefore we have the following equation, \(A \sqrt{2 \mathrm{G}} \sqrt{\mathrm{H}-y}=\) \(A \sqrt{2 G} \sqrt{\frac{x(H-y)}{y}}+D \sqrt{\frac{x}{H}}\). From this we deduce the value of \(x\)
\[
=\frac{2 \mathrm{GHA}}{}\left(\mathrm{~A} \sqrt{2 \mathrm{G}} \sqrt{\left.\frac{\mathrm{H}-y}{y}+\frac{\mathrm{D}}{\sqrt{\mathrm{H}}}\right)^{2}+2 \mathrm{GA}^{2}}\right. \text {. This va- }
\]
lue of \(x\) being fubftituted in the equation of the difcharge \(\delta\) of the branch, which was \(=D \sqrt{\frac{\alpha}{H}}\), will give the difcharges required, and they will differ fo much the more from the difcharges calculated according to the fimple theory, as the velocity in the main is greater. By the fimple theory, we mean the fuppofition that the lateral difcharges are fuch as would be produced by the head \(\mathrm{H}-\hbar\), where H is the height of the refervoir, and \(\%\) the head due to the actual velocity in the main.

And thus it appears that the proportion of the difcharge by a lateral pipe from a main that is flut at the far end, and the difcharge from a main that is open, depends not only on the preffures, but alfo on the fize of the lateral pipe, and its diftance from the sefervoir. When it is large, it greatly alters the train of the main, under the fame head, by altering the difcharge at its extremity, and the velocity in it beyond the brunch; and if it be near the refervoir, it greatly alters the train, becaufe the diminifhed velocity takes place through a greater extent, and there is a greater diminution of the refiftances.

When the branch is taken off at a confiderable diftance from the refervoir, the problem becomes more complicated, and the head \(x\) is refolved into two parts; one of which balances the refiftance in the firlt part of the main, and the other balances the refiftances beyond. the lateral pipe, with a velocity diminimed by the difcharge from the branch.-A branch at the end of the main produces very little change in the train of the pipe.

When the lateral diccharge is great, the train may be fo, altered, that the remaining part of the main will not run full, and then the branch will not, yield the fame quantity. The velocity in a very long horizontal tube may be fo fmall (by a fmall head of water and great obitructions in a yery long tube) that it will juft run full. An orifice made in its upper fide will yield nothing; and yet a fruall tube inferted into it will carry a column almof as high as the refervoir, So that we cannot judge in all cafes of the preffurcs by the difcharges, and vice jerga.

Watce works
"If there be an inclined tube, having a head greater than what is competent to the velocity, we may bring it into train by an opening on its upper fide near the refervoir. This will yield fome water, and the velocity will diminifl in the tube till it is in train. If we thould now enlarge the hole, it will yield no more water than before.

And thus we have pointed out the chief circumftances which affeet thefe lateral difcharges. The difcharges are afterwards modified by the conduits in which they are conticyed to their places of deftination. Thefe being generally of fmall dimenfions, for the fake of economy, the velocity is much diminifhed. But, at the fame time, it approaches nearer to that which the fame conduit would bring directly from the refervoir, becaule its fmall velocity will produce a lefs change in the train of the main conduit.

We fhould now treat of jets of water, which fill make an ornament in the magnificent pleafure grounds of the wealthy. Some of thele are indeed grand objects, fuch as the two at Peterhoff in Rullia, which fpout about 60 feet high a column of nine inches diameter, which falls again, and thakes the ground with its blow. Even a fpout of an inch or two inches diameter, lancing to the height of 150 feet, is a gay object, and greatly onlivens a pleafure-ground; efpecially when the changes of a gentle breeze bend the jet to one fide. But we have no room left for treating this fubject, which is of fome nicety; and mult conclude this article with a very fhort account of the management of water as an active power for impelling machinery.

\section*{II. Of Machinery driven by Water.}

This is a very comprehenfive article, including almoft every poffible fpecies of mill. It is no lefs important, and it is therefore matter of regret, that we cannot enter into the detail which it deferves. The mere defcription of the immenfe variety of mills which are in general ule, would fill volumes, and a fcientific defcription of their principles and maxims of conftruction would almoft form a complete body of mechanical fcience. But this is far beyond the limits of a work like ours. Many of thefe machines have been already defcribed under their proper names, or unde: the articles which give an account of their manufactures; and for others we mutt refer our readers to the original works, where they are defribed in minute detail. The great academical collection Des Arts et Metiers, publifhed at Paris in many folio volumes, contains a defcription of the peruliar ma. chinery of many mills; and the volumes of the Encyclopédie Methodique, which particularly relate to the mechanic arts, already contain many more. All that we can do in this place is, to confider the chicf circumfances that are common to all water-mills, and from which all mut derive their efficacy. Thefe circumflances are to be found in the manner of employing wa'ter as an atting porer, and moft of them' are comprehended in the conftruction of water-wheels. 'When we have explained the principles and the maxims of confruction of a water-wheel, every reader converfant in mechanics knows, that the axis of this wheel may be employed to tranfmit the force imprefted on it to any Species of machinery. "Therefore nothing fublequent to this can with propriety be confidered as zuater-works.

Water-wheels are of two kinds, difinguified by the manner in which water is made an impelling power, viz. by its weight, or by its impulf. This requires a very different form and manner of adaptation; and this forms an oftenfible diftinction, fufticiently obvious to give a name to each clais. Fininen -ater is made to act by its weight, it is delivered from the foout as nighs the wheel as poffible, that it may continue long to prefs it down: but when it is made to frike the wheel, it is delivered as low as poffible, that it may have previoufly acquired a great velocity. And thus the whecls are faid to be overshot or undrinshot.

\section*{Of Over/hot Wheels.}

This is notbing but a frame of open buckets, fo difpofed round the rim of a wheel as to receive the water delivered from a fpout; fo that one fide of the wheel is loaded with water, while the other is empty. The confequence mut be, that the loaded fide muft defcend. Ey this motion the water runs ont of the lower buckets, while the empty buckets of the rifing fide of the wheel come under the fpout in their turn, and are filled with water.

If it were poffible to conftruet the buckets in fuch a manner as to remain completely filled with water till they come to the very bottom of the wheel, the preflure with which the water urges the wheel round its axis would be the fame as if the extremity of the horizontal radius were continually loaded with a quantity of water fufficient to fill a fquare pipe, whofe fection is equal to that of the bucket, and whofe length is the diameter of the wheel. For let the buckets BD and EF (fig. 5.) Fig. 5. be compared together, the arches DB and EF are equal. The mechanical energy of the swater contained in the bucket EF, or the preffure with which its weight urges the wheel, is the fame as if all this water were hung on that point T of the horizontal arm CF, where it is cut by the vertical or plumb-line BI. This is plain from the molt elementary principles of mechanics. Therefore the effect of the bucket BD is to that of the bucket EF as C' to CF or CB. Draw the horizontal lines \(\mathrm{PB} b b, \mathrm{QD} d d\). It is plain, that if BD is taken very fmall, fo that it mav be confidered as a fraight line, \(\mathrm{BD}: \mathrm{BO}=\mathrm{CB}: \mathrm{BP}\), and \(\mathrm{EF}: b d=\mathrm{CF}: \mathrm{CT}\), and \(\mathrm{EF} \times \mathrm{C} \Gamma=b d \times \mathrm{CF}\). Therefore if the prifin of water, whofe vertical fection is \(b b d d\), were hung on at F , its force to urge the wheel round would be the fame as that of the water lying in the bucket BD. The fame may be faid of every bucket; and the effective preffure of the whole ring of water A \(f\) HKFI, in its natural fituation, is the fame with the pillar of water \(a h h a\) hung on at \(F\). And the effect of any portion BF of this ring is the fame with that of the correfponding fortion \(b\) F fb of the vertical pillar. We do not take into accnunt the fmall difference which arifes from the depth B or \(F f\), becaufe we may fuppofe the circle defcribed through the centres of gravity of the buckets. And in the farther profecution of this fubject, we flall take fimilar liberties, with the view of fimplifying the fubject, and faving time to the reader.

But fuch a fate of the wheel is impofible. The bucket at the very top of the wheel may be completely filled with water; but when it comes in:o the oblique pofition BD, a part of the water muft run over the outer edge \(\delta\), and the bucket will only retain the quain-

\section*{W A T} tity \(\mathrm{ZBD} \delta\); and if the buckets are formed by partitions, directed to the axis of the wheel, the whole water
murt be run out by the time that they defcend to the level of the axis. To prevent this many contrivances have been adopted. The whecl has been furrounded with a hoop or feweep, confiling of a circular board, winit comes almon into contact with the rim of the wheel, and terminates at H , where the water is allowed to ruṇ off. But unlefs the work is executed with uncommon accuracy, the wheel made exactly round, and the fiveep exactly fitting it, a great quantity of water efcapes between them; and there is a very fenfible obfrruction to the motion of fuch a wheel, from fomething like friction between the water and the fweep. Froft alfo effectually flops the motion of fuch a wheel. Sweeps lave therefore been generally laid afide, although there are fituations where they might be ufed with good effect.
- Mill-wrights have turned their whole attention to the giving a form to the buckets which fhall enable thera to retain the water along a great portion of the circumference of the wheel. It would be endlefs to defribe all thefe contrivances; and we thall therefore content ourfelves with one or two of the moft approved. The intelligent reader will readily fee that many of the circumftances which concur in producing the ultimate effect (fuch as the facility with which the water is received into the buckets, the place which it is to occupy during the progrefs of the bucket from the top to the bottom of the wheel, the readinefs with which they are evacuated, or the chance that the water has of being oragred beyond the bottom of the wheel by its adhefion, \&c. \&c.) are fuch as do not admit of precife calculation or reafoning about their merits; and that this or that form can feldom be evidently demoniftrated to be the very befl poffible. But, at the fame time, he will fee the general reafons of preference, and his attention will be directed to circumflances which muft be attended to, in order to have a good bucketed wheel.

Fig. 6. is the outline of a wheel having 40 buckets. The ring of board contained between the concentric circles QDS and PAR, making the ends of the buckets, is called the Shrouding, in the language of the art, and QP is called the deptly of frouding. The inner circle PAR is called the Sole of the wheel, and ufually confifts of boards nailed to ftrong wooden rings of compafs timber of confiderable fcantling, firmly united with the Aras or radii. The partitions, which determine the form of the buckets, confilt of three different planes or boards \(\mathrm{AB}, \mathrm{BC}, \mathrm{CD}\), which are varionfly named by differcht artifts. We have heard them named the Start or Shoulder, the Ara, and the Wrest (probably for wrift, on account of a refemblance of the whole line to the human arm); \(\mathbf{B}\) is alfo called the Elbow. Fig. 7. reprefents a fmall portion of the fame bucketing on a larger fcale, that the proportions of the parts may be more diftinatly feen. AG, the fole of one bucket, is made about \(\frac{1}{5}\) th more than the depth GH of the flrouding. The fart \(A B\) is \(\frac{\pi}{\psi}\) of \(A I\). The plane \(B C\) is fo inclined to \(A B\) that it would pafs through \(H\); but it is made in terminate in C , in fuch a manaer that FC is the of GH or AI. Then CD is fo placed that HD is about \(\frac{1}{5}\) th of IH.

By this conftruction, it follows that the aren FABC is scry nearly equal to DABC; fo that the wates
which will gll the fpace FABC will all be contained in the bucket when it thall come into fuch a 'pofition' that \(A D\) is a horizontal line; and the line \(A B\) will then make an angle of nearly \(35^{\circ}\) with the vertical; or the bucket will be \(35^{\circ}\) from the perpendicular. If the bucket defcend fo much lower that one half of the water runs out, the line \(A B\) will make an angle of \(25^{\circ}\), or \(24^{\circ}\) nearly, with the vertical. Therefore the wheet, filled to the degree now mentioned, will begin to lofe water at about \(\frac{1}{8}\) th of the diameter from the bottom, and half of the water will be difcharged from the lowert bucket, about \(\frac{\pi}{27}\) th of the diameter farther down. Thefe fituations of the difcharging bucket are marked at \(I^{i}\) and V in fig. 6. Had a greater proportion of the buickets been filled with water when they were under the Epout, the difcharge would have begun at a greater height from the bottom, and we flould lofe a greater portion of the whole fall of water. The lofs by the prefent confruction is lefs than \(\mathrm{T}^{\mathrm{T}}\) th (fuppofing the wa. ter to be delivered into the wheel at the very top), and may be eftimated at about \(\frac{1}{1}\) th ; for the lofs is the verfed fine of the angle which the radius of the bucket makes with the vertical. The verfed fine of \(35^{\circ}\) is nearly \(\frac{\text { rith }}{5}\) th of the radius (being 0.1808 ), or \(\frac{\mathrm{r}}{\text { Tol }}\) th of the diameter. It is evident, that if only \(\frac{5}{2}\) of this water were fupplied to each bucket as it paffes the fpout, it would have been retained for \(10^{\circ}\) more of a revolution, and the lofs of fall would have been only about \({ }^{2}{ }^{2}\) th.

Thefe obfervations ferve to fhow, in general, that an advantage is gained by having the buckets fo capacious that the quantity of water which each can receive as it paffes the fpout may not nearly fill it. This may be accomplifhed by making them of a fufficient length, that is, by making the wheel fufficiently broad between the two Ihroudings. Economy is the only objection to this practice, and it is generally very ill placed. When the work to be performed by the wheel is great, the addition of power gained by a greater breadth will foon compenfate for the additional expence.

The third plane CD is not very frequent; and millwrights generally content themfelves with continuing the board all the way from the elbow B to the outer edge of the whee' at \(H\); and \(A B\) is generally no more than one-third of the depth AI. But CD is a very evident improvement, caufing the wheel to retain a very fenible addition to the water. Some indeed roake this addition more confiderable, by bringing BC more outward, fo as to meet the rim of the wheel at \(H\), for inflance, and making HD coincide with the rim. But this makes the entry of the water fomewhat more difficult during the very thort time that the opening of the bucket paffes the fpout. To facilitate this as much as polfible, the water thould get a direction from the fpout, fuch as will fend it into the buckets in the mont perfect manner. This may be obtained by delivering the water through an aperture that is divided by thin plates of board or metal, placed in the proper pofition, as we have reprefented in fig. 6. The form of bucket lant mentioned, having the wreft concentric with the rim, is unfavourable to the ready admifion of the watcr; whercas an oblique wreft conducts the water which has miffed one bucket into the next below.
The mechanical confideration of this fabject alfo fhow:s us, that a deep fhrouding, in order to make a capacious bucket,

\section*{W A TV [ 669 ] W A T}

Watere: bucket, is not a good-method: it does not make the works: =r. buckets retain their water any longer ; and it diminiftes the effective fall of, water : fur the water received at the top of the wheel immediately falls to the bottom of the bucket, and thus fortens the fictitious pillar of water, which we fhowed to be the meafure of the effective or uleful preffure on the wheel: and this concurs with our former, reafons, for recommending as great a breadtlo of the wheel, and length of buckets, as economical confiderations will permit.

A bucket wheel was fome time ano executed by \(\mathbf{M r}\) Hobert Burns, at the cotton mills of Houfton, Burns, and Co. at Cartfide in Kenfrewfhire, of a conftruction en. tirely new, but founded on a good principle, which is "ig. 8. fufeeptible of great extention. It is reprefented in fig. 8. The bucket confifts of a fart \(A B\), an arm BC, and a wref CD , concentric with the rim. But the bucket is alfo divided by a partition LM, concentric with the fole and rim, and fo placed as to make the inner and outer portions of nearly equal capacity. It is evident, without any farther reafoning about it, that this partition will enable the bucket to retain its water much longer. When they are filled one-third, they retain the whole water at \(18^{\circ}\) from the bottom; and they retain one half at \(1 L^{\circ}\). They do nol admit the water quite fo freely as buckets of the common conftruction; but by means of the contrivance mentioned a little ago for the fpout (alfo the invention of Mr Burns, and furnified with a rackwork, which raifed or depreffed it as the fupply of water varied, fo as at all times to employ the whole fall of the water), it is found, that a flow-moving wheel allows one-half of the water to get into the inner buckets, efpecially if the partition do not altogether reach the radius drawn through the lip D of the outer bucket.

This is a very great improvement of the bucket wheel; and when the wheel is made of a liberal breadth, fo that the water may be very flallow in the buckets, it fecms to carry the performance as far as it can go. Mr Burns made the firftrial on a wheel of 24 feet diameter ; and its performance is manifelly fuperior to that of the wheel which it replaced, and which was a very good one. It has alfo another valuable property: When the fupply of water is very fanty, a proper adjuflment of the apparatus in the fpout will dired almoft the whole of the water into the outer buckets; which, by placing it at a greater diftance from the axis, makes a very fenfible addition \(t 0\) its mechanical energy.

We faid that this principle is fufecptible of confiderable extenfion; and it is evident that two partitions will increafe the effect, and that it will increale with the number of partitions ; fo that when the practice now begun, of making water-wheels of iron, nlall become general, and therefore very thin partitions are ufed, their number may be greatly increafed without any inconvenience : and it is obvious, that this feries of partitions muft greatly contribute to the ftiffnefs and general firmnefs of the whole wheel.

There frequently occurs a difficulty in the making of bucket wheels, when the half-taught mill-wright attempts to retain the water a long time in the buçkets. The water gets into them with a difficulty which he cannot account for, and fpills all about, even when the buckets are not moving away from the fout. This arifes from the air, which muft find its way out to admit the water, but is obllucted by the entering water, and oc-
cafions a great fputtering at the entry. This may be en. tirely prevented by making the foout confiderably nap. rower than the wheel. This will leave room at the two ftruction is vaftly greater than one would imagine ; for the water drags along with it a great quantity of air, as is evident in the Water-blafl delcribed by many nuthors.

There is another and very ferious obftruetion to the motion of an overfhot or bucketed whicel. When it moves in back water, it is not only refifted by the wa? ter, when it moves more fowly than the wheel, which is very frequently the cafe, but it lifts a great deal in the rifing huckets. In fome particular fates of back water, the defcending bucket fills itfelf completely with water ; and, in other cales, it contains a very confider. able quantity, and air of common denfty; while in fome rarer cafes it contains lefs water, with air in a condenfed fate. In the firft cafe, the rifing bucket mult come up filled with water, which it cannot drop till its mouth get out of the water. In the fecond cafc, part of the water goes out before this; but the air rarefies, and therefore there is fill forne water dragged or lifted. up by the wheel, by fuction as it is ufually called. In the laft cafe there is no fuch back load on the rifing fide of the wheel, but (which is as detrimental to its per. formance) the defcending fide is employed in condenf: ing air ; and although this air aids the alcent of the rifing fide, it does not aid it fo much as it impedes the defcending fide, being (by the form of the bucket) nearer to the verlical line drawn through the axis.

All this may be complctely prevented by a few hole: made in the fturt of each bucket. Air being at lealt 800 times rarer than water, will efcape through a hole almolt 30 times fafter with the fame preffure. Very moderate holes will therefore fuffice for this purpofe : and the fmall quantity of water which thefe holes difcharge during the defcent of the buckets, produces a lofs which is altogether infignificant. The water which runs out of one runs into another, fo that there is only the lofs of one bucket. We have feen a wheel of only 14 feet diameter working in nearly three feet of back water. It laboured prodigioully, and brought up a great load of water, which fell from it in abrupt dafkes, which rendered the motion very hobbling. When three holes of an inch diameter were made in each bucket ( 12 feet long), the wheel laboured no more, there was no more plunging of water from its rifing fide, and its power on the machinery was increafed more than one-fourth.

Thefe practical obfervations may contain information that is new even to feveral experienced mill-wrights. To perfons lefs informed they cannot fail of being ufeful. We now proceed to confider the action of water thus lying in the buckets of a wheel; and to afcertain its energy as it may be modified by different circumfances of fall, velocity, \&xc.

With refpect to variations in the fall; there can be little room for difcuffion. Since the active prcfiure is meafured by the pillar of water reaching from the horizontal plane where it is delivered on the wheel, to the horizontal plane where it is fpilled by the wheel, it is evident that it muft be proportional to this pillar, and therefore we muf deliver it as high and retain it as long as poffible.
'This maxim obliges ns, in the firt place', ta ufe a nticel works.
wheel whofe diameter is equal to the whole fall. We thall not gain any thing by employing a larger wheel ; for although we fhould gain by ufing only that part of the circumference where the weight will ast more perpendicularly to the radius, we thall lofe more by the neceflity of difcharging the water at a greater height from the bottom: For we mut fuppofe the buckets of both the wheels equally well conftructed ; in which cafe, the beights above the bouom, where they will difcharge the water, will increafe in the proportion of the diameter of the wheel. Now, that we hall lofe more by this than we gain by a more direct application of the weight, is plain, without any further reafoning, by taking the extreme cafe, and fuppofing our wheel enlarged to fuch a fize, that the ufelefs part below is equal to our whole fall. In this cafe the water will be fpilled from the buckets as foon as it is delivered into them. Ail intermediate cafes, therefore, partake of the imperfection of this.

When our fall is exceedingly great, a wheel of an equal diameter becomes enormoully big and expenfive, and is of itfelf an unmanageable load. We have feen wheels of 58 feet diameter, however, which worked extremely well; but they are of very difficult conftruction, and extremely apt to warp and go out of thape by their weight. In cafes like this, where we are unwilling to lofe any part of the force of a frall Atream, the beft form of a bucket wheel is an inverted chain pump. Iriftead of employing a chain pump of the beft conftruc-
upright pipe \(\cdot \mathrm{CB}\), by means of a force applied to the upper wheel A , iet the water be delivered from a fpout F , into the upper part of the pipe BC , and it will prefs down the plugs in the lower and narrower bored part of it with the full weight of the column, and efcape at the dead level of C . This weight will urge round the wheel A without any defalcation: and this is the moft power. ful manner that any fall of water whatever can be applied, and exceeds the moft perfect overfhot wheel. But though it excels all chains of buckets in eeonomy and in effect, it has all the other imperfections of this kind of -machinery. Though the ehain of plugs be of great Areng th, it has fo much motion in its joints that it needs frequent repairs; and when it breaks, it is generally in the neighbourhood of A , on the loaded fide, and all comes down with great a crafh. There is allo a lofs of power by the immerfion of fo many plugs and chains in the water; for there can be no doubt but that if the plags were big enough and light enough, they would buoy and even draw up the plugs in the narrow part at C. They muif therefore diminini, in all other cates, the force with which this plug is preffed down.
The yelacity of an overhot wheel is a matter of very great nicety ; and authoris', both feceulative and practical, have entertained different, nay oppofite, opinionis on the fubject. Mr. Belidor, whom the "engineers of Europe have lông been accuffomed to regard as lacred authority, maintain's, that there is a certain velocity related to that obtainable by the whole fall, "which will procure to an overfiot wheel the.greatel performance. Defaguliers, Smeaton, Lambert, De Parcieux, and others, maintain, that there is no fuch relation, and that the performance of an overfhot wheel will be the gireater, as it moves more" noully by an increafe of its load of work. \({ }^{17}\) - Belidor maintains, that the active power of wa-
ter lying in a bucket whecl of any diameter is cqual to that of the impulfe of the fame water on the foats of an underfhot wheel, when the water iflues from a fluice in the bottom of the dam. The other writers whom we have named affert, that the energy of an underiliot wheel is but one half of that of an overlhot, actuated by the fame quantity of water falling from the fame height.

To a manufacturing country like ours, which derives aftonilling fuperiority, by which it more than compenfates for the impediments of heavy taxes and luxurious livirg, chietly from its machinery, in which it leaves all Europe far behind, the decifion of this queftion, in fuch a manner as ftall leave no doubt or mifconception in the mind even of an unlettered artit, mult be confidered as a material fervice: and we think that this is eafily attainable.

When any machine moves uniformly, the accelerating force or preffure actually exerted on the impelled point of the machine is in equilibrio with all the reffitances which are exerted at the working point, with thofe arifing from friction, and thofe that are excited in different parts of the machine by their mutual actions. This is an inconteftable truth; and though little attended to by the mechanicians, is the foundation of all practical knowledge of machines. Thetefore, when an overfhot wheel moves uniformly, with any velocity whatcver, the water is acting with its whole weight : for gravity would accelerate its defcent, if not completely balanced by fome reaction; and in this balance gravity and the reacting part of the machine exert equal and oppofite preffures, and thus produce the uniform motion of the machine. We are thus particular on this point, becaufe we obferve mechanicians of the firt name cmploying a mode of reafoning on the queftion now before us which is fpecious, and appears to prove the conclufion which they draw ; but is neverthelefs contrary to true mechanical principles. They affert, that the flower a heavy body is defcending (fuppofe in a fcale fufpended from an axis in peritrochea), the more does it prefs on the fcale, and the more does it urge the machine round: and therefore the flower an overfhot wheel turns, the greater is the force with which the water urges it round, and the more work will be done. It is very true that the machine is more forcibly impelled, and that more work is done: bat this is not becaufe a pound of water preffes more Arongly, but becaufe there is more water preffing on the, wheel; for the fout fupplies at the fame rate, and each bucket receives more water as it paffes by it.

Let us therefore examine this point by the unque. ftionable principles of mechanics.

Let the overthot wheel Af H (fig. 5.) reccive the Fig. 5. water from a pout at the very top of the wheel; and, in order that the wheel may not be retarded by dragging into motion the water fimply laid into the uppermoft bucket at \(A\), let it be received at \(B\), with the velocity (directed in a tangent to the wheel) acquired by the head of water AP. This velocity, therefore, muft be equal to that of the rim of the wheel. Let this be i, or let the whal and the water move over \(y\) inches in a fecond. Let the buckets be of fuch dimenfions, that all the water which each receives as it paffes the foout is retained till it comes to the pofition \(R\), where it is difcharged at once. It is plain that, in place of the feparate quantities of water lying in each hucket, we may fublitute a continued ring of water, equal to their
fum,

This conflitutes a ring of uniform thicknefs. Let the area of its crofs fection \(\beta \mathrm{B}\) or \(\mathrm{F} f\) be called \(a\). We have already demonftrated, that the mechanical energy with which this water on the circumference of the wheel urges it round, is the fame with what would be exerted by the pillar \(b+r b\) preffing on \(F f\), or acting by the lever \(\mathrm{CF}_{\text {. }}\). The weight of this pillar may be expreffed by \(a \times b r\), or \(a \times P S\); and if we call the radius CF of the wheel \(R\), the momentum or mechanical energy of this weight will be reprefented by \(a \times P S \times R\).

Now, let us fuppofe that this wheel is employed to raife a weight W, which is fufpended by a rope wound sound the axis of the wheel. Let \(r\) be the radius of this axle. Then \(\mathrm{W} \times r\) is the momentum of the work. Let the weight rife with the velocity \(u\) when the rim of the wheel turns with the velocity \(i\), that is, let it rife \(z\) inches in a fecond.

Since a perfect equilibrium obtains between the power and the work when the motion is uniform, we mult have \(W \times r=a \times P S \times R\). But it is evident that \(R: r=v: u\). Therefore \(\mathrm{W} \times u=a \times v \times \mathrm{PS}\).

Now the performance of the machine is undoubtedly meafured by the weight and the height to which it is raifed in a fecond, or by \(\mathrm{W} \times u\). Therefore the machine is in its beft poffible ftate when \(a \times v \times\) PS is a maxinum. But it is plain that \(a \times v\) is an invariable quantity; for it is the cubic inches of water which the fpout fupplies in a fecond. If the wheel moves faft, little water lies in each bucket, and \(a\) is fmall. When \(y\) is finall, \(a\) is great, for the oppofite reafon; but \(a \times v\) remains the fame. Therefore we muft make PS a maximum, that is, we muft deliver the water as high up as poffible. But this diminifhes AP; and this diminifles the velocity of the wheel :- and as this has no limit, the propofition is demonfrated; and an overthot wheel does the more work as it moves floweft.

Convincing as this difcuffion muft be to any mechanician, we are anxious to imprefs the fame maxim on the minds of practical men, unaccufomed to mathematical reafoning of any kind. We therefore beg indulgence for adding a popular view of the queftion, which requires no fuch invefligation.

We may reafon in this way: Suppofe a wheel having 30 buckets, and that fix cubic feet of water are delivered in a fecond on the top of a wheel, and difcharged without any lofs by the way at a certain height from the bottom of the wheel, Let this be the cafe, whatever is the rate of the wheel's motion'; the buckets being of a fufficient capacity to hold all the water which falls into them. Let this wheel be empioyed to raife a weight of any kind, fuppofe water in a chain of 3 ó buckets, to the fame height, and with the fame velocity. Suppofe, farther, that when the load on the rifing fide of the machine is one half of that on the wheel, the wheel makes four turns in minute, or one turn in I'5 fecands. During this fime 90 cubic feet of Water have flowed into the 30 buchets, and each lias received three cubic feet. Then each of the rifing buckets contain's \(\frac{1}{2}\) feet ; and \(45^{\prime \prime}\) cubic feet are delivered into, the upper ciftern during one turn of the iwhéel; and 180 cubic feet in one minute.

No'w, fuppole the machine lo loaded, by making the rifing buckets more capacious, that it makes onty tro torns in a minute, or one turn in 30 feconds. Then
cach defeending bucket mu\{t contain fix cubic feet of water. If each bucket of the rifing fide contained three cubic feet, the motion of the machine would be the fame as before. Ilhis is a point which no mechanician will controvert. When two pounds are fufpended to one end of a ftring which paffes over the pull:y, and one pound to the other end, the defeent of the two pound will be the fame with that of a four pounds weight, which is employed in the fame manner to draw up two pounds. Our machine would therefore continue to make four turns in the minute, and would deliver 90 cubic feet during each turn, and 360 in a minutc. But, by fuppofition, it is making but two turns in a minute: this mult proceed from a greater load than three cubic feet of water in each rifing bucket. 'The machine mult therefore be raifing more than 90 feet of water during one turn of the wheel, and more than 180 in the minute.

Thus it appears, that if the machine be turning twice as llow as before, there is more than twice the former quantity in the rifing huckets, and more will be raifed in a minute by the fame expenditure of power. In like manner, if the machine go three times as forv, there mult be more than three times the former quantity of water in the rifing buckets, and more work will be done.

But we may go-farther, and affert, that the more we retard the machine, by loading it with more work of a fimilar kind, the greater will he its performance. This does not immediately appear from the prefent difcuftion: But let us call the firg quantity of water in the rifng bucket \(A\); the water raifed by four turns in a ininute will be \(4 \times 30 \times A_{1}=120 \mathrm{~A}\). The quantity in this bucket, when the machine gocs twice as flow, has been Nhown to be greater than \(2 A\) (call it \(2 A+x\) ); the water raifed by two turns in a minute will be \(2 \times 30\) \(\times 2 A+1=120 A+60 \therefore\). Now, let the machine go four times as flow, making but one turn in a minute, the rifing bucket mult now contain more than twice \(2 A+x\), or more than \(4 A+2 x\); call it \(4 A+2 x+y\). The work done by one turn in a minute will now be \(30 \times 4 A+2 x+y=120 A+60 x+30 y\).

By fuch an induction of the work, done with any rates of motion we choofe, it is evident that the performance of the maxhine increafes with every diminution of its velocity that is produced by the mere addition of a fimilar load of work, or that it does the more work the flower it goes.

We have fuppofed the machine to-be in its flate of permanent uniform mation. If we confider it only in the beginning of its motion; the refult is fill more in favour of flow motion: For, at the firft action of the moving pouer, the inertia of the machine itfelf confumes patt of it," and it acquires its permanent fpeed by degrees; during which, the refiftances arifing from the work frittion, \&c. increalc, till they exactly balance the preflure of the water; and afier this the machine accelerates no more, Now the greater the power and the reffance arifing from the work are, in proportion to the inertia of the machine, the fooner will all arrive at its ftate of permanent velocity
-There is another circumfance which impairs the performance of an verhot wheel moving yith a great yelocity, viz the effects of the centrifugal force on the

\section*{W A T} water in the buckets. Our mill-wrights know well enough, that too great velocity will throw the water out of the buckets; but few, if any, know exactly the diminution of power produced by this caufe. The following very fimple conllruction will determine this:
Fig. 10. Let AOB (ig. 1o.) be an overhat whee, of which
mathematicians: but they have yielded; and we fee them adopting maxims of conltruction more agreable to found theory; making their wheels of great breadtl, and loading them with a great deal of work. Mr Euler fays, that the performance of the beft mill cannot exceed that of the worlt above f \(^{\text {th }}\) : but we liave feen a Aream of water completely \(\epsilon x\) pended in driving a fmall tlax mill, which now drives a cotton mill of 4000 fpindles, with all its carding, roving, and drawing machinery, befides the lathes and other engines of the fmith and carpenters workllops, eserting a force not lefs than ten times what fufficed for the flax mill.

The above difcuffion only demonftrates in general the advantage of llow motion; but does not point out in any degree the relation between the rate of motion and the work performed, nor even the principles on which it depends. Yet this is a fubject fit for a mathematical invelligation; and we would profecute it in this place, if it were neceffary for the improvement of practical mechanics. But we have feen that there is not, in the nature of things, a maximum of performance attached to any particular rate of motion which thould therefore be preferred. For this reafon we omit this difcuffion of mere fpeculative curionty. It is very intricate: For we mult not now exprefs the preflure on the wheel by a conflant pillar of water incumbent on the extremity of the horizontal arm, as we did before when we fuppoled the buckets completely filled; nor by a fmaller conflant pillar, correfponding to a fmaller but equal quantity lying in every bucket. Each different velocity puts a different quantity of water into the bucket as it paffes the fpout ; and this occafions a difference in the place where the difcharge is begun and completed. This circumftance is fome obftacle to the advantages of very flow motions, becaufe it brings on the difcharge fooner. All this may indeed be expreffed by a fimple equation of eafy management ; but the whole procefs of the mechanical difcuffion is both intricate and tedious, and the refults are fo much diverfified by the fo:ms of the buckets, that they do not afford any rule of futicient generality to reward our trouble. The curious reader may fee a very full inveftigation of this fubject in two differtations by Elvius in the Sucdifh Trantactions, and in the Hydrodynamique of Profefior Karftner of Gottingen ; who has abridged thefe Difiertations of Elvius, and confiderably improved the whole invelligation, and has added fome comparifons of his deductions with the actual performance of fome great works. Thefe comparifons, however, are not very fatisfactory. There is alfo a valuable paper on this fubject by Mr Lambert, in the Memoirs of the Academy of Berlin for the year 1775. From thefe differtations, and from the Hydrodynamigue of the abbe Boflut, the reader will get all that theory can teach of the relation between the preffures of the power and work on the machine and the rates of its motion. The practical reader may reft with confidence on the fimple demonflation we have given, that the performance is improved by diminilhing the velocity.

All we have to do, therefore, is to load the machine, and thus to diminifl its feed, unlefs other phyfical circumflances tbrow obflacles in the way: but there are fuch obftacles. In all machines there are littlc inequalities of action that are unavoidable. In the action of a wheel and pinion, though made with the ntmoft judgment and care, there are fuch inequalities. Thefe in-

AB is the upright diameter, and C is the centre. Make CF the length of a pendulum, which will make two vibrations during one turn of the wheel. Draw FE to the elbow of any of the buckets. The water in this bucket, inftead of having its furface horizontal, as NO, will have it in the direction \(n \mathrm{O}\) perpendicular to FE very nearly.

For the time of falling along half of FC is to that of two vibrations of this pendulum, or to the time of a revolution of the wheel, as the radius of a circle is to its circumference : and it is well known, that the time of moning along lalf of \(A C\), by the uniform action of the centrifugal force, is to that of a revolution as the radius of a circle to its circumference. Therefore the time of defcribing one half of AC by the centrifugal force, is equal to the time of defcribing one half of FC by gravity. Thefe fpaces, being fimilatly deferibed in equal times, are proportional to the accelerating forces. Therefore \(\frac{\pi}{2} \mathrm{FC}: \frac{1}{2} \mathrm{AC}\), or \(\mathrm{FC}: \mathrm{AC}=\) gravity : centrifugal force. Complete the parallelogram FCEK. A particle at \(E\) is urged by its wcight in the direction KE, with a force which may be expreffed by FC or KE ; and it is urged by the centrifugal force in the direction \(C E\), with a force \(=\mathrm{AC}\) or CE. By their combined action it is urged in the direction FE. Therefore, as the furface of fanding water is always at right angles to the action of gravity, that is, to the plumb-line, fo the furface of the water in the revolving bucket is perpendicular to the action of the combined force FE.

Let NEO be the pofition of the bucket, which juft holds all the water which it received as it paffed the fpout when not affected by the centrifugal force; and Iet NDO be its pofition when it would be empty. Let the vertical lines through \(D\) and \(E\) cut the circle defcribed round C with the radius CF in the points H and I. Draw HC, IC, cutting the circle AOB in \(L\) and M. Make the arch \(d^{\prime \prime} \delta\) equal to \(A L\), and the arch \(e^{\prime}\); equal to \(A M\) : Then \(C \delta\) and \(C \&\) will be the pofitions of the bucket on the revolving wheel, correfonding to CDO and CEO on the wheel at refl. Water will begin to run out at \(\varepsilon\), and it will be all gone at 8.-The demonftration is evident.

The force which now urges the wheel is fill the weight really in the buckets: For though the water be urged in the direction and with the force FE, one of its conlituents, CE, has no tendency to impel the wheel; and KE is the only impelling force.

It is but of late years that mills have been conftructed or attended to with that accuracy and fcientific Akill which are neceffary for deducing confidential conclutions from any experiments that can be made with them; and it is therefore ro matter of wonder that the opinions of mill-wrights have been fo different on this fubject. There is a natural wifh to fee a machine moving brifkly; it has the appearance of activity: but a very flow motion always looks as if the machine were overloaded. For this reafon mill-wrights have always yielded nowly, and reith fome reluctance, to the repeated advices of the
creafe by the changes of form occafioned by the wearing of the machinc-much greater irregularities arife from the fubfultory motions of cranks, llampers, and other parts which move unequally or reciprocally. A machine may be fo loaded as jufl to be in equilibrio with its work, in the favourable pofition of its parts. When this changes into one lefs favourable, the machine may slop ; if not, it at lealt ftaggers, hobbles, or works unequally. The rubbing parts bear long on each other, with enormous prefliures, and cut deep, and incteafe friction. Such flow motions mull therefore be avoided. A little more velocity enables the machine to get over thole increafed refiftances by its incrtia, or the great quantity of motion inherent in it. Great machines poffefs this advantage in a fuperior degree, and will therefore work feadily with a fmaller velocity. Thele circumltances are. hardly fufceptible of mathematical dilcuffion, and our belt reliance is on well directed experience.

For this purpafe, the reader will do well to perufe with care the excellent paper by Mr Smeaton in the Philofophical Tranfactions for 1759 . This differtation contains a numerous lift of experiments, moft judicioully contrived by him, and executed with the accuracy and attention to the mof important circumtances, which is to be obferved in all that gentleman's performances.

It is true, thefe experiments were made with fmall models; and we mult not, without great caution, transfer the refults of fuch experiments to large works. But we may fafely transfer the laws of variation which refult from a variation of circumftances, although we mult not adopt the abfolute quantities of the variations themfelves. Mr Smeaton was fully aware of the limitations to which conclufions drawn from experiments on models are fubject, and has made the applications with his ufual hagacity.

His general inference is, that, in fmaller works, the rim of the overthot-wheel fhould not have a greater velocity than three feet in a fecond; but that larger mills may be allowed a greater velocity than this. When every thing is executed in the beft manner, he fays that the work performed will amount to fully two-thirds of the power expended; that is, that three cubic feet of water defcending from any height will raife two to the lame height.

It is not very eafy to compare thefe deductions with obfervations on large works; becaufe there are few cales where we have good meafures of the refiftances oppoled by the work performed by the machine. Mills employed for pumping water afford the bell opportunities. But the inertia of their working gear diminifhes their ufeful performance very fenfibly; becaule their great beams, pump-rods, \&cc. have a reciprocating motion, which muft be deftroyed, and produced anew in every ftroke. We have examined fome machines of this kind which are eifeemed good ones; and we find few of them whofe performance excceds one half of the power expended.

By comparing other mills with thefe, we get the beft information of their refifances. The comparifon with mills worked by Watt and Boulton's fteam-engines is perhaps a better meafure of the refifances oppoled by different kinds of work, becaufe their power is very diltinctly known. We have been informed by one of the mont eminent engineers, that a ton and a half of , Vos. XX. Part II.
water per minute falling one foot will grind and drefs one bulhel of wheat per hour. This is erquivalent to 9 tons falling 10 feet.

If an overflot wheel oppofed un refflance, and only one bucket were filled, the wheel would acquire the velucity due to a fall throtagh the whole height. But when it is in this llate of accclerated motion, if another bucket of water is delivered into it, its motion suat be checked at the fint, by the necelfity of dragging forward this water. If the uuckets fill in fucceffion as they pals the fpout, the velocity acquired by :n unrealling wheel is but half of that which one bucket would give. In all cafes, therefore, the velocity is dimimilued by the inertia of the entering water when it is fimply laid into the upper buckets. The performance will therefore be improved by delivering the water on the wheel with that velocity with which the wheel is really muving. And as we cannot give the direction of a tangent to the wheel, the velocity with which it is delivered on the wheel mut be fo much greater than the intendedovelocity of the rim, that it thall be precifely equal to it when it is eltimated in the direction of the tangent. 1hree or four inches of fall are fufficient for this purpofe; and it thould never be neglected, for it has a very fenfibie iufluence on the performance. But it is highly improper to give it more than this, with the view of impelling the wheel by its flrohe. For even although it were proper to employ part of the fall in this way (which we Thall prefintly fee to be very improper), we cannot procure this impulfe; becaufe the water falls among other water, or it flrikes the boards of the wheel with fuch obliquity that it cannot produce any fuch effect.

It is a much debated queftion among mill-wrights, Whether the diameter of the wheel nould be fuch as that the water will be delivered at the top of the wheel ? or larger, fo that the water is reccived at fome diltance from the top, where it will act more perpendicularly to the arm ? We apprehend that the abfervations formerly made will decide in favour of the fitf practice. The fpace below, where the water is difcharged from the wheel, being proportional to the diameter of the wheel, there is an undoubted lofs of fall attending a large wheet; and this is not compenfated by delivering the water at a greater diftance from the perpendicular. We fhould therefore recommend the ufe of the whole defcending fide, and make the diameter of the wheel no greater than the fall, till it is fo much reduced that the centrifugal force begins to produce a fenfible effect. Since the rim can hardly have a fmaller velocity than three feet per fecond, it is evident that a fmall wheel muft revolve more rapidly. This made it proper to infert the determination that we have given, of the lofs of power produced by the centrifugal force. But eveit with this in view, we thould employ much fmaller wheels than are generally done on fmall falls. Indeed the lofs of water at the bottom may he diminimed, by nicely fitting the arch which furrounds the wheel, fo as not to allow the water to efcape by the fides or bottom. While this improvement remains in good order, and the wheel entire, it produces a very fenfible effect; but the paflage widens continually by the wearing of the wheel. A bit of tick or ftone falling in about the wheel tear off part of the flrouding or bucket, and frofty weather frequently binds all falt. It therefore feldrm anfwers expectations. We have nothing to add on this cale

\section*{W iA T [ 674 ] W A T}

Waterworks.
to what we have already extracted from Mr Smeaton's Differtation on the Subject of Breaft or half Uverllot Wheels.

There is another form of wheel by which water is made to act on a machine by its weight, which merits confideration. This is known in this country by the name of Barker's mill, and has been defcribed by Defaguliers, vol. ii. p. 460 . It confits of an uptight pipe
Fig. i1. or trunk \(A B\) (fig. 11.), communicating with two horizontal branches \(\mathrm{BC}, \mathrm{B} c\), which have a hole \(\mathrm{C} c\) near their ends, opening in oppofite directions, at right angles to their lengihs. Suppofe water to be poured in at the top from the lpout \(F\), it will run out by the holes \(C\) and \(c\) with the velocity correfponding to the depth of thefe holes under the furface. The confequence of this mult be, that the arms will be preffed backwards; for there is no folid furface at the hole C , on which the lateral prefluse of the water can be exerted, while it acts with its full force on the oppofite fide of the arm. This unbalanced preflure is equal to the weight of a column having the orifice for its bafe, and twice the depth under the furface of the water in the tronk for its lecight. This meafure of the height may feem odd, becaufe if the orifice were fout, the preflure on it is the weight of a column reaching from the furface. But when it is open, the water iffues with nearly the velocity acquired by falling from the furface, and the quantity of motion produced is that of a column of twice this length, moving with this velocity. This is actually produced by the preflure of the fluid, and mult therefore be accomspanied by an equal reaction.

Now fuppofe this apparatus fet on the pivot \(E\), and to have a fpindle \(A D\) above the trunk, furnithed with a cylindrical bobbin \(D\), having a rope wound round it, and paffing over a pulley \(G\). A weight \(W\) may be fufpended there, which may balance this backward preffure. If the weight be too fmall for this purpofe, the retrograde motion of the arms will wind up the cord, and raife the weight; and thus we obtain an acling machine, employing the preffure of the water, and applicable to any purpofe. A runner millitone may be put on the top of the fpindle ; and we thould then produce a flour mill of the ulmoll fimplicity, having neither wheel nor pinion, and fubject to hardly any wear. It is fumewhat furprifing, that although this was invented at the beginning of this century, and appears to have fuch advantage in point of fimplicity, it has not come into ufe. So little has Dr Defaguliers's account been attended to (although it is mentioned by him as an excellent machine, and as highly inftructive to the hydraulif), that the fame invention was again brought forward by a German profeflor (Segner) as his own, and has been honoured by a feries of elaborate difquifitions concerning its theory and performance by Euler and by John Bernoulli. Euler's Differtations are to be found in the Memoirs of the Academy of Berlin, 1751 , \&c. and in the Nov. Comment. Petropol. tom. vi. Bernoulli's are at the end of his Hydraulics. Both thefe authors agree in faying, that this machine excels all other methuds of employing the force of watet. Simple as it appears, its true theory, and the beft form of confruction, are moft abflrufe and delicate fuljeets; and it is not eafy to give fuch an account of its principles as will be underftood by an ordinary reader.
We fee, in general, that the machine muft prefs back-
wards; and littic inveftigation fuffices for undentanding the intenfity of this preffure, when the machine is at teft. But when it is allowed to run backwards, withdrawing itfelf from the preffure, the intenfity of it is diminifhed; and if no other circumflances intervened, it mighl not be difficult to fay vihat particular preffure conrefponded to any rute of motion. Accordingly, Defagulicrs, prefuming on the fimplicity of the machine, affirms the preflure to be the weight of a column, which would produce a velocity of efllux equal to the difference of the velocity of the fluid and of the machine ; and hence he deduces, that its performance will be the greaten pol:fible, when its retrograde velocity is one-third of the velocity acquired by falling from the furface, in which cafc, it will raile \({ }^{8}\) ths of the water expended to the fame height, which is double of the performance of a mill acted on by the impulfe of water.

But this is a very imperfect account of the operation. When the machine (contructcd exactly as we have defcribed) moves rourd, the water which illues defeends in the vertical trunk, and then, moving along the horizontal arms, partakes of this circular motion. This ex. cites a centrifugal force, which is exerted againft the ends of the arms by the intervention of the tluid. The whole fluid is fubjected to this preflure (increafing for every fection acrols the arm in the propurtion of its diftance from the axis), and every praticle is preffed with the accumulated centrifugal torces of all the fections that are nearer to the axis. Every fection therefore fuftains an actual preflure proportional to the fquare of its diftance from the axis. This increafes the velocity of efliux, and this increafes the velocity of revolution; and this mutual co-operation would feem to terminate in an infinite velocity of both motions. Buts on the other hand, this circular motion muft be given anew to every particle of water as it enters the horizontal arm. Jhis can be done only by the motion already in the arm, and at its expence. 'Thus there mult be a relacity which cannot be overpaffed even by an unloaded machine. But it is alfo plain, that by making the horizontal arm very capacious, the motion of the water from the axis to the jet may be made very now, and much of this diminution of circular motion prevented. Accordingly, Euler has recommended a form by which this is done in the moft eminent degree. His machine confifts of a hollow conoidal ring, of which fig. 12. is a fection. The part AH \(h a\) is a fort of a funnel bafon, which receives the water from the fpout F ; not in the direction pointing towards the axis, but in the direction, and with the precife velocity, of its mution. This prevents any retardation by dragging forward the water. The water then paffes down between the outer conoid AC ca and the inner conoid HG \(g /\) along fpiral channels formed by partitions foldered to both conoids. The curves of thefe channels are determined by a theory which aims at the annihilation of all unneceflary and improper motions of the water, but which is too abitrufe to find a place here. The water thus conducted arrives at the bottom \(\mathrm{CG}, \mathrm{cg}\). On the the outer circumference of this bottom are arranged a number of ifpouts (one for each clannel), which are all directed one way in tangents to the circumference.

Adopting the common theory of the reaction of fluids, this thould be a very powerful machine, and thould raife eqths of the water cxpended. .But if we admit the reaction
adion to be equal to the force of the iltuing fluid (and we dhat fee how this can. be refufed), the machine mull be nearly twice as powerful. We therefore repeat our wonder, that it has not been brought into ufe. But it appears that no trial has been made even of a model ; fo that we have no experiments to encourage an engineer to repieat the trial. Even the late author, Profeftor Seguer, has not related any thing of this kind in his Exercitationes Hydraulice, whese be particularly defcribes the machine. This remifluef probably has proceeded from fixing the attention on Lulcr's improved confruction. It is plain that this muft be a molt cumbrous mafs, even in a fmall fize requiring a prodigions veffel, and carrying an unwieldy load. If we examine the theory which recommends this confrustion, we find that the advantages, though real and fenfible, bear but a fmall proportion to the whole performance of the finple machine as invented by \(\mathrm{D}_{\mathrm{r}}\) Barker. It is therefore to be regretted, that engineers have not attempted to realize the firft projec. We beg leave to recommend it, with an additional argument taken from an addition made to it by Mr Mathon de la Cour, in Rozier's Jourmal de Pluysique, January and Augult 1775. This
Fig. 13. gentleman brings down a large pipe FEH (fig. 13.) from a refervoir, bends it upward at H , and introduces it into two honizontal arms DA, DB, which have an upright findle DK, carrying a milltone is the ftyle of Dr Barker's mill. 'The ingenious mechanician will have no difficulty of contriving a method of joining thefe pipes, fo as to permit a frce circular motion without lofing much water. The operation of the machine in this form is evident. The water, prefled by the column FG, flows out at the holes A and B , and the unbalanced preffure on the oppofite fides of the arms forces them round. The compendioufnefs and other advantages of this confluction are mof ftriking, allowing us to make ule of the greatef fall without any increale of the fize of the machine. It undoubtedly enables us to employ a fream of water too fcanty to be employed in any other form. The author gives the dimenfions of an engine which he had feen at Bourg Argental. AB is 92 inches, and its diameter 3 inches; the diameter of each orifice is \(\frac{5}{6} ; F G\) is 21 feet; the pipe \(D\) was fitted into \(C\) by grinding; and the internal diameter of \(D\) is 2 inches.

When the machine was performing no work, or was unloaded, and emitted water by one hole onily, it made I' 5 turns in a minute. This gives a velocity of 46 feet per fecond for the ho'e. This is a curious fact: For the water would iffue from this hole at reft with the velocity of \(37 \frac{\pi}{\sigma^{\circ}}\). This great velocity (which was much lefs than the velocity with which the water actually quitted the pipe) was undoubtedly produced by the prodigious centrifugal force, which was nearly 17 times the weight of the water in the orifice.

The empty machine weighed 80 poinds, and its weight was half-fupported by the upper preffure of the Wrater, fo that the friction of the pivots was much diminilled. It' is a pity that the author has given no account of any work done by the machine. Indeed it was only working ventilators for a large hall.. His theory by no means embraces all its principles, nor is it well-
 We think that the free motion round the neck of the feeding-pipe, without any lofs of water or: any confider.
able friction, may be obtained in the fullowing manner : AB (fig. 14.) reprefents a portion of the revolving horizontal pipe, and CE ec part of the feeding pipe. The neck of the firf is turned truly cylindrical, fo as to turn eafily, but without thake, in the collar C c of the feed. ing-pipe, and each has a thoulder which may fupport the other. That the friction of this joint may nut be great, and the pipes defroy each other by wearing, the horirontal pipe has an iron foindle EF, fixed cxatly in the axis of the joint, and refting with its pivot \(F\) in a flep of hard Acel, fixed to the iron bar GH, which goc* acrofs the feeding-pipe, and is firmly fupported in it. This pipe is made bell-fhaped, widening below. A collar or hofe of thin leather is fitted to the infide of this pipe, and is reprefented (in fection) by LKM \(m k l\). 'Ihis is kept in its place by means of a metal or wooden ring \(N n\), thin at the upper edge, and taper haped. This is drawn in above the leather, and ftretches it, and caufes it to apply to the fide of the pipe all around. There can be no lealeage at this joint, becaufe the water will prefs the leather to the f:nooth metal pipe; nor can there be any fenfible friction, becaufe the water gets at the edge of the leather, and the whole unbalanced preffure is at the fmall crevice, between the two metal hhoulders. Thefe moulders need not touch, fo that the friction muf be infemfible. We imagine that this method of tightening a turning joint may be ufed with great advantage in many cafes.

We have only further to obferve on this engine, that any imperfection by which the paffage of the water is diminithed or obfructed produces a faving of water which is in exact proportion to the diminution of effect. The only inaccuracy that is not thus compenfated is when the jets are not at right angles to the atms.

We repeat our wifhes, that engineers would endeavour to bring this machine into ufe, feeing many fituations where it may be employed to great advantage: Suppofe, for inftance, a fmall fupply of water from a great beight applied in this manner to a centrifugal pump, or to a hair belt paffing over a pulley, and dipping in the water of a deep well. This would be a bydraulic machine exceeding all others in fimplicity and durability, though inferior in effect to fome other confructions.

\section*{2. Of Under fino IWhecls.}

All wheels go by this name where the motion of the water is quicker than that of the partitions or boards of the wheel, and it therefore impels them. Thefe are called the font-boards, or floats, of an underfhot wheel. The water, running in a mill-row, with a velocity derived from a head of water, or from a declivity of channel, ftrikes on thefe floats, and occafions, by its deflections fidewife and upwards, a preffure on the floats fuif. cient for impelling the wheel.

There are few points of practical mechinics that have been more confidered than the action of rater on the floats of a wheel; hardly a book of mechanics being filent on the fubject. But the generality of them, at leaft fuch as are intelligible to perfons who are not very much converfant in dynamical and mathernatical difcuffion, have bardly done any thing more than copied the earlief deductions from the fimple theory of the refiftance of fluids. The confequence has been, tbat eur practical knowledge is very imperfect; and it is fill
\(4 Q 2\)
chiefly

Water.
werk:
 works.
chietiy from experience that we muft learn the periormance of underthot uheels. Uufortunately this fops their improvement; becaule thole who bave the only opportunifies of making the experiments are not fuffciently acquainted with the principles of hydraulics, and are apt to afcribe differences in their performance to triiling nollrums in their contruction, or in the manner of applying the impulfe of the water.

We have faid fo much on the imperfection of our theories of the impulfe of tluids in the article RESISTANCE of Fhids, that we need not repeat here the defects of the common explanations of the motions of undermot wheels. The part of this theory of the impulfe of fluids which agrees beft with obfervation is, that the impulfe is in the duplicate proportion of the velocity with which the water ftrikes the float. That is, if \(v\) be the velocity of the flream, and \(z\) the velocity of the float, we thall have \(F\), the impulfe on the Hoat when held falt to its impulle \(f\) on the float moving with the velocity \(u\), as \(v^{2}\) to \(\overline{v-u^{2}}\), and \(f=\mathrm{F} \times \frac{\overline{v-u^{2}}}{v^{2}}\).

This is the preflure acting on the float, and urging the wheel round its axis. The wheel muft yield to this motion, if the refilance of the work does not exert a fuperior preffare on the float in the oppofite direction. Ry yielding, the float withdraws from the impulfe, and this is therefore diminifhed. The wheel accelerates, the refiftances increafe, and the impulfes diminilh, till they become an exact balance for the refiftances. The motion now remains uniform, and the momentum of impulfe is equal to that of refiftance. The performance of the mill therefore is determined by this; and, whatever be the conftruftion of the inill, its performance is beft when the momentum of impulle is greateft. This is had by multiplying the preffure on the foat by its velocity. Therefore the momentum will be expreffed by \(\mathrm{F} \times \frac{\overline{v-u^{2}}}{\mathcal{V}^{2}} \times \pi\). But fince F and \(v^{2}\) are conftant quantities, the momentum will be proportional to \(u \times v \overline{V^{2}}\). Let \(x\) reprefent the relative velocity. Then \(y-x\) will be \(=u\), and the momentum will be proportional to \(\overline{v-x}\) \(\times x^{2}\), and will be a maximum when \(\overline{v-x} \times x^{2}\) is a maximum, of when \(v x^{2}-x^{3}\) is a maximum. This will be difcovered by making its fluxion =o. That is,
\[
2 v x x-3 x^{2} x=0
\]
and \(22 x-3 x^{2}=0\)
or \(2 v-3 x=0\)
and \(2 v=3 x\), and \(x=\frac{2}{3} v\); and therefore \(v-x\), or \({ }^{3},=\frac{7}{3} v\). That is, the velocity of the float mult be one third of the velocity of the ftream. It only remains 10 fay what is the abfolute preffure on the float thus circumfanced. Let the velocity \(v\) be fuppofed to arife from the preflure of a head of water \(h\). The common theory teaches that the impulfe on a given furface \(S\) at rell is equal to the weight of a column \(h \mathrm{~S}\); put this in place of F , and \(\frac{4}{7} \cdot v^{2}\) in place of \(\overline{v-u^{2}}\) and \(\cdot \frac{\pi}{3} v\) for, \(u\). This gives us \(S h \times \frac{4}{2} \frac{0}{0}\) for the momentum. Now the poner expended is \(\mathrm{S} h v\), or the column \(\mathrm{S} / /\) moving with thẹ velocity \(\%\). Therefore the greatell performance of an underfhot wheel is equivalent to railing \(\frac{4}{8}\) of the water that drives it to the fame height.

But this is too fmall an eftimation; for the preffure exerted on a plane furface, fituated as the foat of a mill-
wheel, is conffiderabiy greater than the weight of the co. \%. Water- \(i\) lumn \(S h\). Ihis is nearly, the preffure on a funface \(r_{1} 4\) works.. wholly immerfed in the flud. But when a fmall veln, Atrikts a larger plane, fo as to be deflected on all fides in a tinn theet, the impulfe is almort double of this, This is in fome meafure the cale in a mill wheel. When the ftream Ilrikes it, it is heaped up along its face, and falls back again-and during this motion it is acting with a bydroflatic preflure on it. Wheu the wheel dips into an open river, this accumulation is lefs remarkable, becaufe much efcapes laterally. But in a mill courfe it may be confiderable.

We have confidered only the action on one float, but feveral generally act at once. The impulfe on molt of then mult be oblique, and is therefore lefs than when the fame fiream impinges perpendicularly ; and this diminution of impulfe is, by the common theory, in the proportion of the fine of the obliquity. For this reafon it is maintained, that the impulfe o! the whole fteam on the lowelf floatboard, which is perpendicular to the Afream, is equal to the fum of the impulles made on all the floats which then dip into the water; or that the impulfe on any oblique toat is precifely equal to the im. pulfe which that part of the fream would have made on the lowelt floatboard had it - not been interrupted. Therefore it has been recommended to make fuch a number of floatboards, that when one of them is at the bottom of the wheel, and perpendicular to the fream, the next in fucceffion hould be juit entering into the water. But fince the impulfe on a float by no means annihilates all the motion of the water, and it bends round it and hits the one behind with its remaining force, there mult be fome advantage gained by employing a greater number of floats than this rule will permit. This is abundantly confumed by the experiments of Smeaton and Buffut. Mr Boffut formed three or four fuppofitions of the number of floats, and calculated the impulfe on each; according to the obfervations made in a courle of experiments made by the Academy of Sciences, and inferted by us in the article RESISTANCE of Fluids; and when he fummed them up, and compared the refults with his experiments, he found the agreement very latisfactory. He deduces a general uule, that if the velocity of the wheel is one-third of that of the fream, and if 72 degrees of the circumference are immerled in the Ilream, the wheel fhould have 36 floats. Each will dip one-fifth of the radius. The velocity being fill fuppofed the fame, there fhould be more or tewer floats according as the arch is lefs or gieater than 72 degrees.

Such is the theory, and fuch are the circumfances which it leaves undetermined. 'lhe accumulation of the water on a floatboard, and the force with which it may ftill Atrike another, are too intricate to be affigned with any tolerable precilion: For fuch reafons we nuft acknowledge that the theory of underflot wheels is atill very imperfect, and that recourle mult be had to experience for their improvement: : We therefore ftrongly recommend the perufal of Mr Smeaton's experiments on underthot wheels, contained in the fame differtation with thofe we have quoted on orerfhot wheels. We bave only to obferse, that to an ordinary reader the experiments will appear too much in favour of underfhot wheels, His aim is partly to eflablifh a theory, which will nate the relation betwsen their performance and the velocity

\section*{W A T [ 677 ] W A T}

Where of the fleam, and pattly to thate the relation between wurks. the power expended and the work done. 'Ihe velucity in his experiments is always confiderably below that which a body would acquire by falling from the furface of the head of water; or it is the velocity acquired by a thorter fall. Therefore if we cflimate the pawer expended by the quantity of water multiplied by this diminithed fall, we thall make it too fmall; and the difference in lone cafes is very great : yet, even with thefe concenlions, it appears that the utmolt performance of an underthot wheel does not furpafs the raifing onc-third of the expended water to the place from which it came. It is therefore far inferior to an overthot wheel expending the fame power ; and Mr Belidur has led engineers into very mitlaken maxims of confluction, by faying that overthot wheels thould be given up, even in the cafe of great falls, and that we thould always bring on the water from a fluice in the very bottom of the dam, and bring it to the wheel with as great velocity as pollible. Mr Smeaton alfo fays, that the maximum takes place when the velocity of the wheel is two-fifths of that of the Aream, inftead of two-fixths according to the theory; and this agrees with the experiments of B ffut. But he meafured the velocity by means of the quantity of water which run paft. This mut give a velocity lomewhat too fmall; as will appear by attending to Buat's obfervations on the fuperficial, the mean, and the bottom velocities.

The reft of his obfervations are moft judicious, and well adapted to the initruction of practitioners. We have only to add to them the obfervations of Des Parcieux and Baffut, who have evinced, by very good experiments, that there is a very fenfible advantage gained by inclining the floatboards to the radius of the wheel about 20 degrees, fo that the loweit thatboard thall not be perpendicular, but have its point turned up the flream about 20 degrees. I'his inclination caules the water to heap up along the floatboard, and aet by its rveight. The fluats thould therefore be made much broader than the vein of water interrupted by them is deep.

Some engineers, obferving the great fuperiority of overilot wheels above underthot wheels driven by the fame expence of power, have propofed to bring the water home to the bottom of the wheel on an even bottom, and to make the floatboard no deeper than the aperture of the llaice, which would permit the water to run out. The wheel is to be fitted with a clofe fole and fides, exactly fitted to the end of this trough, fo that if the wheel is at reft, the water mav be dammed up by the fole and floatboard. It will therefore prefs forward, the floatboard with the whole force of the head of water. But this cannot anfwer; for if we fuppofe no fluatboards, the water will flow nut at the bottorn, propelled in the manner thofe perfons fuppofe ; and it will be fupplied from behind, the water coming glowhy from all parts of the trough to the hole below the wheel. But now add the floats, and fuppofe the wheel in motion with the ve: locity that is expected. The other floats mult drag in. to 'motion all the water which lies between them, giving to the greateft part of it a motion valtly greater than it would have taken in confequence of the preflure of the water behind it; and the water out of the reach of the fiazts will remain fill, which it would not have done iudependent of the floatboards above it, becaufe it Fould have contributed to the expence of the hole. The
motion therefore which the wheel will acquire by this Water:" conllruction mull be fo different from what is expected, works. that we can hardly fay what it will be.

We are thereforc perftaded, that the beft way of delivering the water on an underfhot wheel in a clofemillcourle is, to let it flide down a very finooth channel, without tonching the wheel till near the bottom, where the wheel thould be exaetly fitted to the courfe; or, io make the tloats exceedingly broader than the depth of the vein of water which glides down the courfe, and al. low it to be partly intercepted by the firft floats, and heap up along them, acting by its weight, after its inpulle has been expended. If the bottom of the courfe be an arch of a circle defcribed with a radius much greater than that of the wheel, the water which flides down will be thus gradually intercepted by the flaats.

Attempts have been made to conltuet water-wheels which receive the impulfe obliquely, like the fails of a common wind-mill. This would, in many fituations, be a very great acquifition. A very flow but deep river could in this manner be made to drive our mills; and although much power is loll by the obliquity of the impulfe, the remairder may be very great. It is to be segretted, that thefe attempts have not been more zealounly profecuted; for we have no doubt of their fuccefs in a very ferviceable degree. Engineers have been deterred, becaufe when fuch wheels are plunged in an open flream, their lateral motion is too much impeded by the motion of the fream. We have feen one, however, which was very powerful: It was a long cylindrical frame, having a plate flanding out from it about a foot broad, and furrounding it with a very oblique fpiral like a cork-icrew. This was plunged about one-fourth of its diameter (which was about I 2 feet), having its axis in the direction of the flream. By the work which it was performing, it leemed more powerful than a common wheel which occupied the fame breadth of the river. Its length was not leis than 20 feet : it might have been twice as much, which would have doubled its power, without occupying more of the water way. Perhaps fuch a firal, continued to the very axis, and moving in a hollow canal wholly filled by the fream, might be a very adyantageous way of employing a deep and flow flream.

But mills with oblique floats are molt ufeful for employing fmall ftreams, which can be delivered from a Spout with a great velocity. Mr Boflut has confidered thefe with due attention, and afcertained the beft modes of conftudtion. There are two which have nearly equal performances: i. The vanes being placed like thofe of a wind-mill, round the rim of a horizontal or vertical wheel, and being made much broader than the vein of water which is to Atrike them, let the fpout be fo directed that the vein may ffrike them perpendicularly. By this meafure it will be fpread about on the vane in a thin fheet, and exert a preflure nearly equal to twice the weight of a column whofe bafe is the orifice of the fpout, and whofe height is the fall producing the velocity.

Mills of this kind are much in ufe in the fouth of Europe. The wheel is horizontal, and the vertical axis carries the millitone; fo that the mill is of the utmolt fimplicity: and this is its chief recommendation; for its power is greatly inferior to that of a wheel conftruct. in the ufual manner.
2. The vanes nay be arranged round the rim of the wheel,

Waterworks.
wheel, not like the fails of a wind-mill, but in planes inclined to the radii, but parallel to the axis, or to the planes paffing through the axis. They may either ftand on a fole, like the oblique floats recommended by De Parcieux, as above mentioned: or they may fand on the fide of the rim, not pointing to the axis, but afide from it.

This difpofition will admit the fpout to he more conveniently difpofed either for a horizontal or a vertical wheel.
We flall conclude this article ty defcribing a contrivance of Mr Burns, the inventor of the double bucketed wheel, for fixing the arms of a water-wheel. It is well known to mill-wrights that the method of fixing them by making them to pafs through the axle, weakens it exceedingly, and by lodging water in the joint, foons caufes it to rot and fail. They have, therefore, of late years put calt-iton flanches on the axis, to which each arm is bolted: or the flanches are fo fafmioned as to form boxes, ferving as mortifes to receive the ends of the arms. Thefe aniwer the purpofe completely, but are very expenfive; and it is found that arms of fir bolted into flanches of iron, are apt to work loofe. Mr Burns has made wooden fanches of a very curious confruction, which are equally firm, and cof much lefs than the iron ones.

This flanch confifts of eight pieces, four of which compofe the ring reprefented in fig. 15. meeting in the joints \(a b, a b, a b, a b\), directed to the centre 0 . The other four are covered by thefe, and their joints are reprefented by the dotted lines \(\alpha, \beta, \alpha \beta, \alpha \beta, \alpha \beta\). Thefe two rings break joint in fuch a manner that an arm MN is contained between the two nearefl joints \(a^{\prime} b^{\prime}\) of the one, and \(\alpha^{\prime} \beta^{\prime}\) of the other. The tenon formed on the one end of the \(\operatorname{arm} \mathrm{A}, \& \mathrm{c}\). is of a particular thape: one fide, GF, is directed to the centre O ; the other fide, BCDE , has a fmall houlder BC ; then a long fide \(C D\) directed to the centre \(O\); and then a thitd part DE paraflel to GF , or rather diverging a little from it, fo as to make up at E the thicknefs of the fhoulder BC; that is, a line from B to E would be parallel to CD. This fide of the tenon fits exactly to the correfponding fide of the mortile; but the inortifc is wider on the other fide, leaving a face GFK \(h\) a little narrower at FK than at G \(h\). Thefe tenons and mortifes are made extremely true to the fquare; the pieces are put round the axle, with a few blocks or wedges of foft wood put between them and the axle, leaving the face empty oppofite to the place n \(\{\) each arm, and firmly bolted together by bolts between the arm-mortifes. The arms are then put in, and each is preffed home to the fide CDE, and a wedge HF of hard wood is then put into the empty part of the mortife and driven home. When it comes through the Hunch and touches the axle, the part which has come through is cut off with a thin chifel, and the wedge is driven better home. The fpaces under the ends of the arms are now filled with wedges, which are driven home from oppofite fides, till the circle of the arms fands quite perpendicular on the axle, and all is faft. It needs no hoops to keep it together, for the wedging it up round the axte makes the two half rings draw clofe on the arms, and it cannot fart at its own joints till it erufhes the arms. Hoops, however, can do no harm, when all is once wedged up, but it would be improper to put them on before this be clone.

A very curious hydrauic mảchine was erected at Zurich by H. Andreas Wirtz, a tinplate worker of that place. The invention flows him to be'a perfon of very uncommon mechanical knowledge and fagacity. As it is a machine which operates on a principle widely different from all other hydraulic machines, and is really excellent in its kind, we prefume that our readers will not be difpleafed with fome account of it.

Fig. 16 . is a fketch of the fection of the machine, as it was firth erected by Wirtz at a dyehoule in Limmat, in the fuburbs or vicinity of Zurich. It confifts of a hollow cylinder, like a very large grindilone, turning on a horizontal axis, and partly plunged in a ciftern of water. The axis is hollow at one end, and communicates with a perpendicular pipe CBZ', part of which is hid by the cylinder. This cylinder or drum is formed into a fpiral canal by a plate coiled up within it like the main fring of a watch in its box; only the fpires are at a diftance from each other, fo as to form a conduit for the water of uniform width. This fpiral partition is well joined to the two ends of the cylinder, and no water efcapes between them. The outermof turn of the fpiral begins to widen about three-fourths of a circumference from the end, and this gradual enlargement continues from \(Q\) to \(S\) nearly a femicircle: this part may be called the Horn. It then widens fuddenly, forming a Scoop or thovel SS'. The cylinder is fupported fo as to dip feveral inches into the water, whofe furface is reprefented by VV'.

When this cylinder is turned round its axis in the direction ABEO, as exprefled by the two darts, the fcoop \(S^{\prime}\) dips at \(V^{\prime}\), and takes up a certain quantity of water before it emerges again at \(V\). This quantity is fufficient to fill the taper part SQ , which we have called the Horn; and this is nearly equal in capacity to the outermoft uniform fpiral round.

After the fcoop has emerged, the water paffés along the firal by the motion of it round the axis, and drives the air before it into the rifing-pipe, where it efcapes.In the mean time, air comes in at the mouth of the fcoop; and when the fcoop again dips into the water, it again takes in fome. Thus there is now a part filled with water and a part filled with air. Continuing this motion, we fhall receive a fecond round of water and another of air. The water in any turn of the fpiral will have its two ends on a level ; and the air between the fucceffive columns of water will be in its natural flate; for fince the paffage into the rifing-pife or Mass is open, there is nothing to force the water and air into any other pofition. But fince the fpires gradually diminith in their length, it is plain that the column of water will gradually occupy more and more of the circumfe. rence of each. At laft it will occupy a complete turn of fome fpital that is near the centre; and when feint farther in, by the continuance of the motion, fome of it will run back over the top of the fucceeding fpiral. Thus it will run over at \(\mathrm{K}_{4}\) into the right-hand fide of the third fpiral. Therefore it will pufh the water of this fpire backwards, and raife its other end, fo that it alfo will run over backwards before the next turn be completed. And this change of difpofition will at loft reach the firt or outermon fpiral, and fome water will run over into the horn and fooop, and finally into the ciftern.

But as foon as water gets into the rifing-pipe, and

\section*{W A T [ 679] W A - T}
rifes a litule, in it, it Atops the efcape of the air when the next icoop of water is taken in. Here are now two columns of water acting againlt each other by liydroilatic prefliure and the intervening column of air. They mult comprefs the air between them, and the water and air columns will now be unequal. This will have a genesal tendency to keep the whole water back, and caufe it to be lighler on the left or rifing fide of each fpire than on the right deicending fide. The excefs of height will be juft fuch as produces the compreffion of the air between that and the preceding column of water. 'Ihis will go on increafing as the water mounts in the rifingpipe; for the air next to the rifing-pipe is comprolled at its inner end with the weight of the whole column in the main. It muft be as much comprefied at its outer end. This mull be done by the water column without it ; and this column exerts this preflure partly by reafon that \(z\) is outer end is higher than its inner end, and pattly by the tranfmifion of the paflure on its outer end by air, which is fimilarly comprefied from without. And thus it will happen that each column of water, being higher at its outer than at its inner end, comprefles the air on the water colum beyond or within it, which tranfmits this preflure to the air beyond it, adding to it the prellure arifing from its own want of level at the ends. Therefore the greatef compreflion, viz. that of the air next the main, is produced by the fum of all the tranfimitted preflures; and thefe are the fum of all the differences between the elevation of the inner ends of the water columns above their outer ends: and the height to which the water will rife in the main will be juft equal to this fum.

Draw the horizontal lines \(\mathrm{K}^{\prime} \mathrm{K}_{1}\), \(\mathrm{K}^{\prime} \mathrm{K}_{2}\), \(\mathrm{K}^{\prime} \mathrm{K}_{3}\), \&c. and \(m n, m n, m n, \& z c\). Suppofe the left-hand fpaces to bo filled with water, and the right-hand fpaces to be filled with air. There is a certain gradation of compreffion which will keep things in this pofition. The fpaces evidently decreafe in arithmetical progreffion; fo do the hydroflatic beights and preflures of the water columns. If therefore the air be denfe in the fame progreffion, all will be in hydrofatical equilibrium. Now this is evidently producible by the mere motion of the machine; for fince the denfity and compreffion in each air column is fuppofed inverfely as the bulk of the column, the abfolute quantity of air is the fame in all; therefore the column firf taken in will pafs gradually inwards, and the increafing compreflion will ciufe it to occupy precifely the whole right-hand fide of every fpire. The gradual diminution of the water columns will be produced during the motion by the water running over backwards at the top, from fire to fpire, and at laft coming out by the fcoop.

It is evident that this difpofition of the air and water will raife the water to the greatef height, becaufe the bydroftatic height of each water column is the greateft polfible, viz. the diameter of the fipire. This difpolition may be obtained in the following manner : Take CL to CB as the denfity of the external air to its denfity in the lart column next the rifing-pipe or main; that is, make CL to CB as 33 feet (the height of the column of water which balances the atmofpherc), to the fum of 33 feet and the height of the rifing-pipe. Then divide BL into fuch a number of turns, that the fum of their diameters thall be equal to the height of
the main; then bring a pipe ftratght from \(L\) to the centre C. The reaton of all this is very evident.

But when the main is very hogh, this conftruction will require a very great diameter of the drum, or many turns of a very narrow pipe. In luch cales it will be much better to make the fpiral in the form of a corkficrew, as in fig. 17. inted of this Hat form like a watel-fpring. The pipe which forms the fipiral may be lapped round the frullum of a cuat, whole greatell diameter is to the leall (which is next to the raling-pipe) in the fame proportion that we alfigned to CB and CL . By this contruction the water whll tand in every round fo as to have its upper and lower furfaces tangents to the top and bottom of the fipiral, and the water columns will occupy the whole alicending fide of the maclane, while the air occupies the delcending fide.
This form is vaitly preferable to the flat: it will allow us to employ many turns of a large pipe, and therefore produce a grcat elevation of a large quantity of water.

The fame thing will be fill better done by lapping the pipe on a cylinder, and making it taper to the end, in fuch a proportion that the contents of each ruand may be the fame as when it is lapped round the cone. It will raife the water to a greater height (but with an increafe of the impelling power) by the fame number of turns, bec.ufe the vertical or preffing height of each column is greater.
Nay, the fame thing may be done in a more fimple manner, by lapping a pipe of uniform bore round a cylinder. But this will require more turns, becaufe the water columns will have lefs differences between the heights of their two ends. It requires a very minute inveftigation to frow the progrefs of the columns of air and water in this conftruction, and the various changes of their arrangement, before one is attained which will continue during the working of the machine.

We have cliofen for the defcription of the machine that conftruction which made its principle and manner of working moft evident, namely, which contained the fame material quantity of air in each turn of the fpiral, more and more compreffed as it approaches to the rifingpipe. We flould otherwife have been obliged to inveftigate in great detail the gradual progrefs of the water, and the frequent changes of its arrangement, before we could fee that one arrangement would be produced which would remain confant during the working of the machine. But this is not the beft conftruction. We fee that, in order to raife water to the height of a colums of 34 feet, which balances the atmofphere, the air in the latt fire is comprefled into half its bulk; and the quantity of water delivered into the main at each turn is but half of what was received into the firft fire, the reft flowing back from fpire to fpire, and being dif. charged at the fpout.
But it may be confructed fo as that the quantity of water in eacla fire may be the fame that was received into the firlt; by which means a greater quantity (double in the inflance now given) will be delivered into the main, and raifed to the fame height by very nearly the fame force.-This may be done by another proportion of the capacity of the fpires, whether by a change of their caliber or of their diameters. Suppofe the bore to be the fame, the diameter mufl be made fuch that the confant column of water, and the column of air, com-

\section*{W A T [ 680 ] iv A T}

Wrater preited to the proper degree, inay occupy the whole works. circumference. Let \(\Lambda\) be the column of water which
balances the atmofphere, and \(h\) the beight to which the water is to be raifed. Let A be to \(\mathrm{A}+h\) as 1 to m. .

It is plain that \(m\) will reprefent the denffiy of the air in the latt foire, if its natural dentity be I , becaule it is prefled by the column \(A+h\), while the common air is preffed by A. Let 1 repretent the comfant water column, and therefore nearly equal to the air column in the firt feire. The whole circumference of the laft feire muft be \(1+\frac{1}{m}\), in order to hold the water 1 , and the air compreffed into the fpace \(\frac{1}{m}\) or \(\frac{A}{A+i}\).

The circumference of the firft fire is \(1+1\) or 2. Let \(D\) and \(d\) be the diancters of the firf and laft fpires; we have \(2: 1+\frac{1}{m}=\mathrm{D}: d\), or \(2 m: m+1=\mathrm{D}: d\). Therefore if a pipe of uniform bore be lapped round a cone, of which \(D\) and \(d\) are the end diameters, the fpirals will be very nearly fuch as will anfwer the purpofe. It will not be quite exaet, for the intermediate firals will be fomewhat too large. The conoidal fruttum fhould be formed by the revolution of a curve of the logarithmic kind. But the error is very trilling.

With fuch a fiiral, the full quantity of water which was confined in the firt fpiral will find room in the laft, and will be fent into the main at every turn. This is a very great advantage, efpecially when the water is to be much raifed. The faving of power by this change of conftruction is always in proportion of the greatelt compreflion of the air.

The great difficulty in the conftrution of any of thefe forms is in determining the form and pofition of the horn and the fcoop; and on this greatly depends the performance of the machine. The following inftructions will make it pretty eafy.
r゙ig. 15. Let ABEO (fig. 18.) reprefent the frft or outermolt round of the firal, of which the axis is C. Suppofe it immerged up to the axis in the water \(\mathrm{VV}^{\prime}\), we have feen that the machine is moft effective when the furfaces \(K B\) and \(O n\) of the water columns are diftant the whole diameter BO of the fpiral. Therefore let the pipe be firf fuppofed of equal caliber to the very mouth E \(c\), which we fuppofe to be juft about to dip into the water. The furface \(\mathrm{O}_{n}\) is kept there, in oppofition to the preffure of the water column BAO, by the comprefled air contained in the quadrant \(O E\), and in the quadrant which lies behind EB. And this compreftion is fupoorted by the columns behind, between this fpire and the rifing pipe. But the air in the outermoft quadrant EB is in its natural Pate, communicating as yet with the external air. When, however, the mouth E e has come round to \(A\), it will not have the water llanding in it in the fame manner, leaving the half fpace BEO filled with compreffed air; for it took in and confined only what filled the quadrant BE. It is plain, therefore, that the quadrant BE. muft be fo fhaped as to take in and confine a much greater quantity of air ; fo that when it has come to \(A\), the face BEO may contain air fufficiently denfe to fupport the column \(\mathbf{A O}\). But this is not cnough: For when the wide mouth, now at \(A \propto\) rifes up to the top, the furface of the water in it rifes alfo, becaufe the part \(\mathrm{AO} \circ a\) is more ca-
pacious than the cylindric part OE co which fucceeds it, and which cannot contain all the water that it does. Since, then, the water in the fipe rifes above \(\Lambda\), it will prets the water back from \(O n\) to fome other pofition \(m^{\prime} n^{\prime}\), and the prefling licight of the water column will be diminifhed by this rifing on the other fide of O . In thort, the hom nuit begin to widen, not fiom H, but from \(A\), and mult occupy the whole femicircle \(A B E\); and its capacity mut be to the capacity of the oppolite cylindrical fide as the fum of BO , and the height of a column of water which balances the atmofohere to the height of that column. For then the air which filled it, when of the common denfity, will fill the uniform fide BEO , when comprefled fo as to balance the vertical column BO. But even this is not enough; for it has not taken in enough of water. When it dipped into the cittern at E, it carried air down with it, and the preffure of the water in the ciftern caufed the water to cife into it a little way; and fome water mult have come over at B from the other fide, which was drawing narrower. Therefore when the horn is in the pofition EOA, it is not full of water. Therefore when it comes into the fituation OAB , it cannot be full nor balance the air on the oppolite fide. Some will therefore come out at \(O\), and rife up through the water. 'The horn mult therefore, 1l, Extend at leaft from \(O\) to \(B\), or occupy half the circumference; and, 2 dly, It muft contain at leaft twice as much water as would fill the fide BEO. It will do little harm though it be much larger; becaufe the furplus of air which it takes in at E will be difcharged, as the end \(\mathrm{E} e\) of the horn rifes from O to B , and it will leave the precife quantity that is wanted. The overplus water will be difcharged as the horn comes round to dip again into the ciltern. It is poffible, but requires a difcuftion too intricate for this place, to make it of fuch a fize and frape, that while the mouth moves from E to B, palfing through \(O\) and \(A\), the lurface of the water in it thall advance from E to \(\mathrm{O} \pi\), and be exactly at \(O\) when the beginning or narrow end of the horn arrives there.

We mutt alfo fecure the proper quantity of water. When the machine is fo much immerfed as to be up to the axis in water, the capacity which thus fecures the proper quantity of air will alfo take in the proper quantity of water. But it may be erected to as that the firals thall not even reach the water. In this cafe it will anfwer our purpofe if we join to the end of the horn a fcoop or fhovel QRSB (fig. 19.), which is fo formed as to take in at lealt as much water as will fill the horn. This is all that is wanted in the beginning of the motion along the fpiral, and more than is neceffary when the water has advanced to the fueceeding fpire; but the overplus is difharged in the way we have mentioned. At the fame time, it is needlefs to load the machine with more water than is neceffary, merely to throw it out ayain. We think that if the horn occupies fully more than one-half of the circumference, and contains as much as will fill the whole round, and if the foop lifts as much as will certainly fil the horn, it will do very well.
N. B. The froop mutt be very open on the fide next the axis, that it may not confine the air as foon as it enters the water. This would hinder it from receiving water enough.

\section*{W A T [ 681 ] W A T}

The following dimenfions of a machine crected at Florence, and whofe performance correfponded extremely well with the theory, may ferve as an example.

The fipial is formed on a cylinder of 10 feet diameter, and the diameter of the pipe is 6 inches. The fmaller end of the horn is of the fame diameter; and it occupies three-fourths of the circumference, and it is \(\eta \mathrm{r}_{0}{ }^{8}\) ths inches wide at the outer end. Here it joins the fcoop, which lifts as much water as fills the horn, which contains 4340 Swedish cubic inches, each \(=1.577\) Englifh. The machine makes fix turns in a minute, and railes 1354 pounds of water, or 22 cubic feet, 10 feet ligh in a minute.

The above account will, we hope, fufficiently explain the manner in which this fingular hydraulic machine produces its effect. When every thing is executed by the maxims which we have deduced from its principles, we are confident that its performance will correfpond to the theory; and we have the Florentine machine as a proof of this. It raifes more than rioths of what the theory promifes, and it is not perfect. The fpiral is of equal caliber, and is formed on a cylinder. The friction is fo inconfiderable in this machine, that it need not be mended: but the great excellency is, that whatever imperfection there may be in the arrangement of the air and water columns, this only affects the elegance of the execution, caufing the water to make a few more turns in the fpiral before it can mount to the height required; but waftes no power, becaufe the power employed is always in proportion to the fum of the vertical columns of water in the rifing fide of the machine; and the height to which the water is raifed by it is in the very fame proportion. It fhould be made to move very flow, that the water be not always dragged up by the pipes, which would caufe more to run over from each column, and diminith the preflure of the remainder.
If the rifing-pipe be made wide, anid thus room be made for the air to efcape freely up through the water, it will rife to the height affigned ; but if it be narrow, fo that the air cannot get. up, it rifes almof as flow as the water, and by this circumftance the water is raifed to a much greater height mixed with air, and this with hardly any more power. It is in this way that we can account for the great performance of the Florentine machine, which is almof triple of what a man can do with the fineft pump that ever was made : indeed the performance is fo great, that one is apt to fufpect fome inaccuracy in the accounts. The entry into the rifingpipe noould be no wider than the laft part of the fipiral; and it would be advifable to divide it into four chennels by a thin partition, and then to make the rifing-pipe very wide, and to put into it a number of flender rods, which would divide it into flender channels that would completely entangle the air among the water. This will greatly increale the height of the heterogeneous column. It is furprifing that a machine that is fo very promifing fhould have attracted fo little notice. We do not know of any being erteted out of Switzerland except at Florence in \(177^{8}\). The account of its performance was in confequence of a very public trial in ' 1779 , and honourable declaration of its merit, by Sig. Lorenzo Ginori, who erected another, which fully equalled it. It is thortly mentioned by Profeffor Sulzer of Ber3in, in the Sammhungen Vermifchlen Schriften for \({ }^{1754}\). A defcription of it is publilhed by the Philofophical So.

Vol. XX. Part II.
ciety at Zurich in 1766 , and in the deferiptions publifhed by the Socicty in London for the encouragement of Arts in 1776. The celebrated Daniel Berruulli has publifhed a very accurate theory of it in the Peterlurgh

works II
Waterland. Commentaries for 1772 , and the machines at Florence were erected according to his infiructions. Baron N. ftromer in Sweden caufed a glafs model of it to be made, to exhibit the internal motions for the inftuction of artifts, and alfo ordered an operative engine to be erect. ed; but we have not feen any account of its petform. ance. It is a very intricate machine in its principles; and an ignorant enginecr, nay the moft intelligent, may erect one which fiall hardly do any thing; and yet, by a very tritling clange, may become very powerful. Whe prefume that failures of this lind have turned the attention of engineers from it; but we are perfuaded that it may be made very effective, and we are certain that it mult be very durable. Fig. 20. is a fection of the man- Fig. \(2 \mathbf{\$}\). ner in which the author has formed the communication between the firal and the rifing-pipe. P is the end of the hollow axis which is united with the folid iron axis Adjoining to P , on the under fide, is the entry from the laft turn of the fpiral. At \(Q\) is the collar which refts on the fupports, and turns round in a hole of tellmetal. If is a broad Hanch cafl in one piece with the hollow part. Beyond this the pipe is turned fomewhat fmaller, very round and fmooth, fo as to fit into the mouth of the rifing-pipe, like the key of a cock. This mouth has a plate ee attached to it. There is another plate \(d d\), which is broader than \(e e\), and is not fixed to the cylindrical part, but moves eanly round it. In this plate are four fcrews, fuch as \(g, g\), which go into holes in the plate \(f f\), and thus draw the two plates \(f f\) and \(d d\) together, with the plate ee between them. Pieces of thin leather are put on each fide of ee; and thus all efcape of water is effectually prevented, with a very mo. derate compreffion and friction.

WATERFORD, a city and fea-port of Ireland, in a county of the fame name, with a bifhop's fee. It is the fecond place in the kingdom, and is a wealthy, populous city, enjoying many ample privileges. The freets are narrow, and the air is not very healthy; but it has an excellent harbour, feated as well for trade as any in the world, and Mips of the greateft burden may ride at the quay. It ftands on the river Sure, 8 miles noth of \(\mathrm{St}_{t}\) George's Channel, 26 fouth of Kilkeniy, and 75 fouth by weft of Dublin. W. Long. 6. 54. N. Lat. 52.18.

Waterford, a county of Ireland, 46 miles in length, and 25 in breadth; bounded on the fouth by St George's Channel ; on the weft by Cork ; on the north by the river Sure, which feparates it from Tipperary and Kilkenny; and on the ealt by Waterford Haven, which parts it from Wexford. It contains 7 I parithes, and fends 10 members to parliament. It is a fine country, very pleafant and rich, and the principal place is of the fame name.

WATERING, in the manufactures, is to give a luftre to ftuff;, \&c. by wetting them lightly with gumwater, and then paffing them through the prefs or calender whether hot or cold. The gum-water ought to be pure, thin, and clear, otherwife the folds of the ftuff will all fick together: the operation mutt alfo be performed when the water is very hot, that it may penetrate.

Whtering Meadows. See Mradowg.
WATERLAND, Dr DANiEl, a leamed Englifh
\[
4 \mathrm{~K} \quad \text { divine }
\]

Whaterland, divine who diflinguilhed himfelf greatly in theological Watron. controverfies, was born in 1683 at Wafely in Lincoln- nire,' of which place his father was rector. He had his academical learning at Magdalen college, Cambridge, where he drew un a ufeful trad, which went through feveral cditions, intitled, Advice to a Young Siudint, with a Method of Surdy for the firl four years. In 1713 he becancemafer of the the college, was foon after appointed chaplain to George I. and in 1720 preached the filf courfe of lectures founded by Lady Moyer in defence of our Lord's divinity. He went through feveral promotions; and at the time of his death in 1740, was canon of Windfor, archdeacon of Middlefex, and vicar of Twickenhans. Befides his controverfial writings, he publihed two volumes of fermons.
WATLING-strfet. See Way.
WATSON, Dr Robert, an elegant hiftoriab, was born at St Andrew's in Scotland, about the year 1730. He was the fon of an apothecary of that place, who was alfo a brewer. Having gore through the uffal courfe of languages and philofophy at the fchool and univerfity of his native place, and alfo entered on the fudy of divinity, a defire of being acquainted with a larger circle of liteati, and of improving himfelf in every branch of knowledge, carried him, firt to the univerfity of Glafgorw, and aficrwards to that of Edinburgh. The period of theological fludies at the univerfilies of Scotland is four years: but during that period, young men of ingenious minds find fufficient leifure to carry on and advance the purfuits of general knewledge. Mr Wation purfued his fudies with ardour. Few men ever fludied more confantly. It was a rule with him to fudy eight hours every day; and this law he obferved during the whole courfe of his life. An acquaintance with the polite writers of EngIand, afler the union of the two kingdoms, became general in Scotland; and in Watfon's younger years, an emulation began to prevail of writing pure and elegant Englifh. Mr Wation applied himfelf with great indufry to the principles of philofophical or univerfal grammar; and by a combination of thefe, with the authority of the bef Englim writers, formed a courfe of leftures on Ryle or language. He proceeded to the ftudy of rhetoric or eloquence; the principles of which he eneleavoured to trace to the siature of the buman mird. He delivered a courfe of lectures in Edinburgh on thefe fubjeets; and met with the countenance, approbation, and friendflip of Lord Kames, Mr Hume, with other men of genius and learning.

At this time he had become a preacher; and a vaeancy having happened in one of the churches of St Andrew's, he offered himfelf a candidate for that living, but was difappointed. Soon after he was appointed prefeflor of logic; and he obtained alfo a patent from the crown, conftituting him profeflor of rhetoric and belles lettres. The nudy of logic, in St Andrews, as in moft other places, was at this time confined to fyllogifins, modes, and figures. Mr Wation, whofe mind had been opened by converfation, and hy reading the writings of the wits that lad begun to flourifi in the Scotch cay ital, prepared and read to his ftudents a courfe of metaphyfics and logics on the moft eulightencd plan; in which he analyzed the powers of the mind, and entered deeply into the nature of the different fpecies of evidence of truth or knowledge. By his hiftory of Philip II. Dr Wation attained in his lifetime a confiderable degree of
celebrity; and his hifory of Philip III. publifited after lis death, has added to his fame.. Oi this laft performance, however, he has only completed the firft four books; the two laft were written by the editor of his maruiccipt, at the defire of the gualdians of his children.

On the death of Piincipal Tulideph, Dr Watfon, through the earl of Kinnoull, was appointed his fuccelfur; in which flation he lived only a few years. He married a lady of fingular beauty and virtuc, daughter to Mr Shaw, profeffur of divinity in St Mary's college, St Andrew's. By this lady he had five daughters, who furvived him.

WAT'TS, Dr Isaac, a learbed and eminent diffen:ing minifter, was born at Southampton in 1674, of parents eminent for piety, and confiderable fuffierers tor conicience-fake. In 1690 he was fent up to London for academical education under the tuition of the Rev. Mir Thomas Rowe; and in 1696 was himfelf engaged as tutor to the fon of Sir John Hartopp, Bart, at Stoke Newington. He began to preach in 1698 , and met nith general acceptance; and after officiating as an af fiftant to the Kev. Dr Ifac Chauncy, he fucceeded in his paftoral charge in 1702, and continued to prefide over that church as long as he lived. Though his uhole income did not amount to an hundred a-year, he allotted one third of it to the poor. He died in 1748. His numerous works have rendered his name fanous ariong people of every denomination, both in this and other countries, and have been traiflated into a valiety of languages. His Lyric Poems, his Pfalms and Iy mns, and his Divine Songs for Children, are a lufficient proof of his poctical talents, and have had an amazing number of editions. His logic and phileforhy have bcen much adnired. He alfo wrote works upon a variety of other fubjects, and printed feveral volumes of his fernoons. He was admired for the mildnefs and benevolence of his difpofition and the fweetnefs of his manners. Aficr his death, his works were collected, and publifhed in fix volumes quarto.

WAVE, in Phitofophy, a cavily in the furface of water, or other fluids, with an elevation afide thereof.

The waves of the fea are of two kinds, natural and accidental. The natural wares are thofe which are exactly proportioned in fize to the flrength of the wind, whofe blowing gives origin to them. The accidental waves are thofe occafioned by the wind's reacting upon itfelt by repercuffion from hills and mountains, or high fhores, and by the wafhing of the waves themfelves, otherwife of the natural kird, againf rocks and moals: all thefe caufes give the waves an elevation, which they can never have in their natural flate. For the height of the waves, Tee Sea.

Stilling IW AVEs by means of Oil. See Sea.
WAVED, in Heraldry, is faid of a bordure, or any ordinary or charge, in a coat of arms, having its outlines indented in manner of the rifing and falling of waves: it is ufed to denote, that the fill of the family in whofe arms it 月ands, acquired its honours by fea-「ervice.

WAVING, in the fea-language, is the making figns to a veffel to come near or kecp off.
WAX, or Bces WAX, in Natural Hifory, a firm and folid fubftance, moderatcly heary, and of a finc yellow colour, formed by the bees from the pollen of flowers. Sce Apis.

Walfic
VI

\section*{W A X [ 68.3 ] W A Y}

The beit fort is that of a lively yellow colour, and an aggreeable fmell, fomewhat like that of honey: when new, it is toughinh, yet ealy to break; but by age it becones harder and more brittle, lofes its fine colour, and in' a grent mealure its fmell.

It appears that wax and the pullen have for their bafis a fat oil, which pafles to the fate of refin by its combination with oxygen. If the nitric or muriatic acid be digetled upon fixed oil for feveral months, it palfes to a date refembling wax. Wax, by repeated diltillations, affurds an oil which pnfiefles all the properties of volatile oils. It is reduced into water and carbonic acid by combution. The colouring matter of wax is infoluble in water and in alcohol.

Fixed alkalies diholve wax, and render it foluble in water. It is this faponaceous folution which forms the punic war. It may be uled as the bafis of feveral colours; and may be made into an excellent pafte for walliing the hands. Ammoniac likewife diftolves it; and as this folvent is cvaporable, it ought to be preferred when it is propofe: to ule the wax as a varnifh.

From the conmon yellow wax, by bleaching, is formed white-wax, fometimes called, very improperly, vir-gin-was. The greater the furface is in proportion to the quantity, the fuoner and more perfectly this operation is performed. The ufual way is to melt the wax in hot water; when melted, they prefs it through a ftrainer of tolerable fine linen, and pour it into round and very thallow moulds. When hardened by cooling, it is taken out and expofed to the fun and air, fprinkling it now and then with water, and often lurning it: by this means it foon becomes white. The beft fort is of a clear and almof tranfparent whitenefs, dry, hard, brittle, and of an agreeable fmell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great ule both in medicine and in many of the arts and manufactures. It has been fometimes given internally in dyfenteries and erofions of the inteftines; but its great ule is in the making ointments and platers, and the greater part of thole of the thops owe their confitence to it. The white wax is allo an ingredient in fome of the cerates and ointments of the fhops; and is ufed in making candles, and in many of the nicer arts and manufactures where wax is required.

Sealing-IVAX, or Spanifb-WAx, is a compofition of gum lac, melted and prepared with refins, and coloured with fome fuitable pigment.

There are two kinds of fealing-wax in ufe; the one hard, intended for fealing letters, and other fuch purpofes; the otber foft, defigned for receiving the impreffions of feals ot office to charters, patents, and fuch written infruments. The belt hard red fealing-wax is made by mixing two parts of hell lac, well. powdered, and refin and vermilion, powdered, of each one part, and melting this combined powder over a gentle fire; and when the ingredients feem thormughly incorporated, working the wax into fticks. Seed lac may be fubtituted for the thell-lac; and intead of refin, boiled Venice turpentine may be ufed. A coarfer, hard, red fealingwax, may be made, by mixing two parts of refir, and of thell-lac, or vermilion and red lead, mixed in the proportion of onc part of the vermilion to two of the red luad, of each one part; and proceeding as in the former preparation. For' a cheaper kind, the vermilion may be
omitted, and the lhell-lac allo, for very coarle ufes. Wax of other colours is made by fubfituting other colvuring matters for vermilion, as verditer for blue, ivory black for black wax. For uncoloured, foft fealing-wax, take of becs wax, one pound; of turpentine, three ounces; and of olive oil one cunce; place them in a proper veftel over the fire, and let them boil for fome time; and the wax will be then fit to be formed into rolls or cakes for ufe. For red, black, green, blue, yellow, and purple loft fealing-was, add to the preceding compof 1 tion an ounce or more of any ingredients dirceted above for colouring the hard fealing-wax, and ftir the mals till the colouring ingredients be incorporated with the wax.

Wrix-Work, the reprefentation of the faces, \&c. of petfons living or dead; made by applying plather of Paris in a kind of palte, and thus forming a mould containing the exact reprefentation of the features. Into this mould melted wax is poured, and thus a hind of malks are formed; which being painted and fet with glafs eyes, and the figures dieffed in their proper habits, they bear fuch a relemblance that it is difficult to diAtinguith between the copy and the original.

WAY, a paflage or road.
The Roman ways are divided into confular, protorian, military, and public; and of thefe we have fuur remarkable ones in England: the firft, Watling-Itreet, or Watheling. Areet, leading from Dover to London, Dunftable, 'Toucefter, Atteriton, and the Severn, extending as far as Anglefea in Wales. The fecond, called Hikenild or lkenild freet, flretches from Southamptor over the river Ilis at Newbridge; thence by Camden and Litchfield; then paffes the Derwent near Derby, and ends at Tinmouth. The third, called Fofe-zvay, becaufe in fome places it was never perfected, but lies as a large ditch, leads from Cornwall through Devon/hire, by Tethbury, near Stow in the Wolds; and befide Coventry to Leicefter, Newark, and fo to Lincoln. The fourth, called Erming or Erminage Areet, extends from St David's, in Wales, to Sruthampton.

War Covert, Gang, Hatch. See Covert Way, GANG, 8:c.

Wir of a Ship, is fometimes the fame as her rake, or run forward or backward: but this term is moit commonly underftood of her failing.

WAr-Leaves, in the cual bulinefs. See Coalery, \(\mathrm{N}^{\mathrm{o}}\).

Righe of WAYS, in Law. This may be grcunded oin a feccial permiltion; as when. the owner of the land grants to another a liberty of paffing over his frounds, to go to church, to market, or the like: in which cafe the gift or grant is particular, and confined to the graritce alone; it dies with the perlon; and if the grantee leaves the country, he cannot afiign over his right to any other; nor can he jultify taking another perion in his company. A way may be allo by prefcription; as if all the owners and occupiers of fuch a farm have immemorially ufed to crofs another's ground; for this immemorial ulage fuppofes an criginal grant, whereby a right of way thus appustenant to land may clearly be created. A right of way may alfo arife by act and operation of law; for if a man grants me a piece of ground in the midjle of his fied, he at the fame time tacitly and impliedly gives me a way to come at it ; and I mas crofs his land for that purpofe without trefpals. For
when the law doth give any thing to one, it giveth imphicdly whatloever is necefliary for enjoying the fame. By: the law of the twelve tables at Rome, where a man thad the right of way over another's land, and the road -was out of repair, he who had the right of way might go over any part of the land he pleafed; which was the eltablifhed:rule in public as well as private ways. And the lave of England, in both cafes, feems to correfpond with the Roman.
Wayparing tree. See Viburnum, Botany Index.

WAYGHTES, or WAITS, a word which is ufed only in the plural number, and fignifies hautboys. It is now applied to the performers on thefe and other mufical initruments, \(b\), a tranfition from the infruments themfelves, and particularly to thofe performers who parade the ftreets by night, about the Chriftmas feafon of the year.

WAYWODE, is properly a title given the governors of the chief places in the dominions of the czar of Muicory. The palatisce, or governors of provinces in Poland, alfo bear the quality of waywodes or waizoodes. The Poles likewife call the princes of Wallachia and Moldavia waywodes; as efteeming them no other than on the foot of governors; pretending that Wallachia and Moldavia are provinces of Poland. Every where elfe thefe are called hofpodars. Du Cange fays, that the name waywode is ufed in Dalmatia, Croatia, and Hungary, for a general of an army : and Leunclavius, in his Pandects of Turkey, tells us, it ufually fignifies captain or commander.

WEANING, putting a child away from the breaf, and hringing it to ufe common food.

WEAR, or. Weer, a great ftank or dam in a river, fitted for the taking of finh, or for conveying the ftream to a mill. New wears are not to be made, or others altered, to the nuifance of the public, under a certain penalty. See River.

Wearing, or Veering, in Seamanfbip. See Seamanship.
Weasel. See Mustela, Mammalia Index.
WEATHER denotes the flate of the atmofiphere with regard to heat and cold, wind, rain, and other meteors. See Meteorology.

Weather, in fea-language, is ufed as an adjective, and applied by mariners to every thing lying to windward of a particular fi: uation : thus, a fhip is faid to have the weather-gage of another, when the is farther to wirdsard. Thus alfo, when a fhip under fail prefents either of her fides to the wind, it is then called the wea-Wher-fide or weather-board; and all the rigging and furniture fituated thercon are diftinguiflied ly the fame epithet, as the wurather-forouds, the weather-lifis, the wea-sher-braces, \&c.

To Weather, in fea-language, is to fail to windward of fome thip, bank, or bead-land.

WEATHER-Cock, a moveable vane, in form of a cock, or other thape, placed on high, to be turned round according to the direction of the wind, and point out the quarter, from whence it blows.
Weather Glafs. See Barometer.
WEATHERING, among failors, fignifies the doubfing or failing hy a head-land or other place. WEAVING, the art of working a web of cloth, alk; or other fuff, ini a loom with a thuttle. For an
idea of the manner in which this is performed, fee Wcarin Сцоти.

II E.fIING-Loom, a machine for weaving cloth, filk, \&ic. by raifing the threads of the warp in order to throw i? the thoot, and Itrike it clofe. Of thefe there are various kinds, diflinguifhed by the different forts of cloths, fluffs, filks, \&c. in which they are employed, and which are chietly diftinguilhed by the number and va. riety of the threads they raife in order to work the warp, either plain or in figures, by making more or lefs of the woof or thoot appear through the warp. In order to give a general idea of weaving, we fhall here defcribe the parts of the cominon weaver's loom. Fig. I. in which ef, ef are the front pofts, and \(g, g\) the back pofts of the loom; \(/ / t, m m, m m\) are the lams in their place at \(Q\), or, as they ate called in fome parts of Scotland, the headles, and in others the flaves. They are compofed of itrong threads, ftretched between two horizontal bars, an upper and a lower. The threads of one lam are fo difpofed as to pals between the upper threads of the warp, while they admit the lower tureads to pafs through loops or fmall holes in them, and the difpofition of the threads of the other lam is fuch, that while they pals between the lower threads of the warp, they admit the upper threads to pats through the fmall holes jult mentioned. The lams are fulpended from the crofs bar or lam-bearer \(H H\), by means of ropes \(n, n\) paffing from the upper bars of the lams over the pulleys at EE, and balanced by weights at the other ends. From the lower bar of each lam or headle a rope paffes to the treadics or moveahle bars at OU ; fo that when a foot preffes a treadle, the lam faflened to it finks, while the other rifes by means of the balancing weight fufpended from the pulley at E. The workman then throws in the woof by means of the Phuttle, and clofes it by one or two ftrokes of the lay or batten, of which WB, II B are called the fwords, CC the cap, or in Scotland the upper fiell, DD the block or under fbell, and PP the reed or comb contained between thefe fhells. LL is the bench on which the workmen fit; for the loom which our figure reprefents is conftructed for weaving cloth of fuch a breadth as to req̧uire two workmen, who have their quills in a box \(d\) on the middle of the bench on which they fit. Between the workmen's hench and the tatten or lay is the breafl-bar I, I, a fmooth fquare beam, in which there is an opening to let the weh through as it is wove. From this opening the web SS paffes to the knee roll or ueb bcam GG, round which it is rolled by means of the fookes; rifible in the figure. and kept from being unrolled by a wheel with teeth and clench, vifible likewife in the figute. In fome looms the web palfes from the knee roll to the wooden frame \(X\), to be dried as it is wove. Oppofite to the breall-bar, and on the other fide of the botton or lay, is the canc-roll or yarn-licam, on which theswarp is rolled when put into the loom, and from which it is gradually unrolled as the work proceeds. TT are bobbins filled with yarn of the warp to mend fuch threads of it as may be broke in the weaving; and \(\mathrm{B} b, \mathrm{~B} b\) are clues of the fame kind of yarn with the borders of the warp, to mend fuch threads as may there be broken.

Fig. 2. reprefents the rommon hutile with the va. cuity in the middle, in which the quill with the woof is placed on a fpindle or axis. As this thuttle is thrown with one hand in' at one fide of the 'riarp, and received with

Plate

\section*{(NV \(E{ }^{-1} A\)}

Wenving. with the other hand at the other fide, it is obvious, that when the web is of a breadth too great for a man to reach from one fide of it to the other, two workmen mult be employed and much time lon. To remedy this inconveniency, a new fhutle has, in this country, been lately brought into very general ufe, and called the flying floutle, becaufe it thies through the warp with wonderful rapidity on two Iteel rollers Pill (fig. 3.) This Thuttle is not thrown with the hand, but moved backwards and forwards by a very fimple piece of machinery, of which fig. 4 . will give the reader a fufficiently accurate conception. To each end of the batten or lay Lh is faftened a kind of open box B, \(b\), with the bottom or horizontal fide exactly on a level with the threads of the warp of the intended web. In each of thefe boxes is a yertical piece of wood \(\mathrm{D}, d\), of confiderable thick'nefs, called a driver. This driver is moved eanty on an iron fininde or axis from one end of the bos to the other by means of a flender rope CCCD, and a handle H is feen in the figure. When the weaver is to begin his work, he lays the fluttle on its rollers in the bos B with the iron tip T (fig. 3.) touching, or almatt touching, the driver D (fig. 4.). Then moving the handle H , with a fudden jerk, towards the box \(b\), the driver D furces the fhuttle with a rapid motion through the warp till it frikes \(d\), which is impelled by the froke to the further end of the hox \(b\). The two drivers D and \(d\) have now changed their pofitions in their refpective boxes; fo that the driver which was at the front of its box before, is now at the further end of it, and vice verfa. Then by a fudden jerk of the hand towards B the fhuttle is driven back till it Atrike D ; and thus is the work continued without the weaver having occafion ever to ftretch his arms from one margin of the web to the other. That the fhuttle may not, by the unfteadinefs of the workman's hand, be drivers xig-xag through the warp or out of the place in which it ought to move, the guiding or driving rope CCCD is made to pals through fmooth holes or loops C, C, at the ends of the ropes EC, EC, fufpended either from the crofs bar on the top of the loom or from the fwords of the batten.

This fhuttle, we fhould think, a great improvement in every kind of weaving loom, though fome of the older tradefmen, with whom we have converled on the fubject, contend, that it is valuable only in what they call light work, fuch as cotton or linen cloth, or when the web, if woollen, is very broad.

But as the labour of weaving is pretty fevere, Mr Robert Millar, an ingenious calico-printer in the county of Dumbarton, Scotland, wihhing to leffen it, invented, fome years ago, a weaving-loom, which may be wrought by water, fleam, horfes, or any other power, for which invention he received a patent in 1796. The following is his own defreription of his patent weavingloom:
Eig. 5. Fig. 5. reprefents a fide view of the loom, A A, BB, CC, DD, being the frame. \(a\) is an axis (which we flall call the fpindle) acrofs the frame. On this axis is a fleeve \(b\), two inches thick, having a groove round it, two inches deep, and half an inch wide. The bottom of this groove is circular, except in one part \(\dot{c}\), where \(i\) is filled up to the top; a lever \(d\) retts on the bottom of this groove, and is lifted up by it when the elevation \(c\) comes round to the fituation reprefented in the figure. By this mation, the lerer dacs on the zatcinct-wheel \(c\)
by the catch \(t\), and draws it forward one tooth, each re- Weavinge; volution of the flseeve. This ratchet-wheel is in an iton frame \(g g\), which alfo properly carries the two catches : and \(u\), which are connected with it at \(v\). The catch \(u\) holds the ratchet-wheel in its pofition, while the lever \(d\) and the catch \(t\), are moved by the groove \(c\) in the fheeve. On the arbor of the ratchet is a fmall pirion \(h\), working in the wheel \(f\); this wheel is fixed on the end of the roller \(e\) of fig. 7. On the fide of the fhecve \(b\) is fixed a wiper \(k\), which lifts the treadle \(7 l\). This treadie turns on its joints in the fheeve \(E\), which is fixed to the fide of the frame A and D ; it is kept prelling on thic hottom of the groove in the fheeve by a fpring \(m\), fixed to the frame fide \(\Lambda\), and having a flender rod \(n\) from its extremity, joining it with the treadle at \(\%\). From the point of the treadle there goes a belt \(o\), which pafies over the pulley \(p\), which is feen edgewife in this figure, and is joined to the top of the fly pin \(q\), of fig. 6. At the end of the frame \(A\) is the fhort poft \(\mathbf{F}\); on this relts the yarn-beam \(j\), having a theeve \(r\), over which paffes a cord, having a weight \(s\) fuppended to it. The other end of this cord is faftened to the fpring \(v\); the weight caufes the yarn-beam to fretch the web from the ratchet-wheel \(e\), with its catch \(u\); and the fpring \(v\) allows the rope to flide on the fleeve as the ratchet is drawn round during the working.

Fig. 6 . is a front view of the loom. \(a a\) is the fpin-Fig. \(G_{2}\) dle which carries the fheeve \(b\), and the wipers \(d\) and \(d\), which move the treadles \(w, w\), of fig. 5 . Thefe ufe the treadles of the headles, with which they are connected by cords from the thafts of the headles \(s, s\). From the upper flaft there go two leathern belts \(f, f\), to the roller \(y\), furnithed each with a buckle, for tightening them at pleafure. The two wipers \(c, c\), on the fhaft \(a\), which ferve for taking back the lay, have the two treadles \(x, x\), in fig. 7 . with a belt from each paifing over the roller \(h 2\) of fig. 6 . and fixed to the fword of the lay. From the fwords of the lay forward is fixed a belt to each end of the roller \(i\); from this roller there goes a cord to the fpring \(j\), which ferves for taking forward the lay which is hinged on the rockingtree 2 . The flar-wheel \(b\) of fig. 3. and the flieeve \(b\) of fig. 2. are fixed to the oppofite ends of the fpindle a without the frame; and both the wheel and Gheeve have a wiper \(k\) fixed to them for moving the treadles.' In order to drive the thuttle, the belts \(o, o\), go from the points of the treadles, over the pulleys \(p_{j}, p\), to the top of the fly-pin \(q\) : This turns-on a pin joint in a rail \(r_{3}\) which goes acrofs the loom. From its lower end there go two fmall cords to the fluttle drivers \(g, g\), which dide on the iron reds \(n, n\). A long iron rod \(s\) goes acrofs the lay, and is hung on two centres at the ends. In this rod \(v\) are fixed two fmall crooked wires \(u v, w\), which are more diffinctly marked in the little Gigure \(w\) above, which reprefents a fection of the lay. The dot at the lower end of the wire \(w\), in this figure, is the fection of the rod \(v\). The thuttle paffes betiveen thefe wires and the lay every fhot, and lifts them up, caufing the rod \(v\) to turn round a little. But if tho fhuttle fhould not pals thefe wires, nor lift them, it would be drawn home by the lay, and deffroy the web. To prevent this, there is fixed on one end of the rod a flout crooked wire \(\approx\), having a broad or flat head, which naturally refts on a plate of iron, marked and fived to the back of the lay, : This :plate has aratilin.

Werying. its middle about an inch deep. In this lit reffs the rod \(a 2\) of fig. 7 . on which is a fhort flud, which is caught by the wire \(\approx\) when the wire \(w\) is not lifted back by the panfing thuttle. This will ftop the lay from coning lome, and will fet of the loom. fig. 5. On the fipindle \(a\) is the flar wheel \(b\), on the outfide of the loom-frame, on the arms of which wheel is fixed the wiper \(k\), as the fimilar wiper is fixed to the fheeves on the other ead of the fpindle. The wipers which drive the thatles are fixed on oppofite fquares of the fpindle, and work alternately. Helow the flarwheel is a pinion \(c\), which is on a round fpindle, turned by the water-wheel, by means of a wheel on this fpindie. In 2 wheel on this fpindle are two lfuds, on which the pinion \(c\) flides off and on, as the loam is fet off and on by the lever \(d\). At the farther end of this lever is the weight \(s\), hanging by a cord which paffes over a pulley \(t\), fixed at the outer end of the fpring-catch on which the lever \(d\) refts; and thus the loom is drawn in at the upper cnd of the lever \(d\). But when the fluatlle does not lift the wire \(z\), it catches on the flud on the \(\operatorname{rod} a 2\), which is connected with the fpring-catch, and the lever \(d\) flics off with the weight \(s\), and the loom flops working. On the head of the poft F is the yarnbeam. The rollers \(e\) and \(f\) are cylinders, preffed together by a fercw-lever, and take away the cloth between them at a proper rate. In the roller \(f\) is a groove for a band for driving the roller \(g\), on which the cluth winds itfelf as it is wrought. Wherever furings are mentioned to be ufed in the above defcription, weights may be uffed in their flead, and to the fame effect, and more efpecially upon the treadle of fig. 5 . for driving the huttle.

Fig. 8. is a reprefentation of a ribband loom. I. Is the frame of the loom. 2. The cafte, containing \(4^{8}\) pulleys. 3. The branches, on which the pulleys turn. 4. The tires, or the riding-cords, which run on the pulleys, and gull up the high-lifes. 5. The lift-fticks, to which the high-lifies are tied. 6. The high-lifics, or lits, are a number of long threads, with platines, or plate-leads at the bottom; and ringlets, or loops, about their midale, through which the cords or crofs-threads of the ground-harnefs rice. 7 . The plate-leads, or platines, are flat pieces of lead, of about fix inches long, and three or four inches broad at the top, but round at the bottom; furne ufe hlack flates inftead of them: their ufe is to pull down thofe liffes which the workman had raifed by the treadle, after his foot is taken off. 8. The branches or cords of the grourd harnefs, which go through the loops in the middle of the high. lifies: on the wall ordering of thefe cords chiefly depends the ant of ribbon-weaving, becaufe it is by means of this contrivance that the weaver draws in the thread or filk that makes the flower, and rejects or excludes the ref. 9. The button: this is the wooden frame that holds the reed or fiuttle, and beats or clofes the work: where, offerve, that the ribboi-weaver does not beat his work; but as fonn as the fluttie is pafted, and his hand is taken away, the batton is forced, by a fpring from the top, to lieat the work clofe. 10. The flutile, or reed. I1. The fpring of the bation, by which it is made to clofe the wort. 12. The long-hamefs are the foont-reeds, by whicli the figure is raifed. 13. The linguas are the lông picces of rouid or fruare lead, ticd to the end of
each thread of the long-harnefs to keep them tight. Weaving 14. The broad piece of wood, about a foot fyutare, leaning fomewhat forward, intended to eafe the weaver as he itoops to his fhuttle; it is fixed in the middle of the breaft-beam. Some weavers, inftead of this, have a contrivance of a cord or rope that is faftened to the front-frame, and comes acrofs his brealt ; this is called a fopfall. 15 . The feat-bench ; this leans forward very much. 16. The foot-ltep to the treadles. 17. The brealt-beam, being a crofs-bar that paffes from one of the flandards to the other, fo as to front the workman's brealt : to this brealt-bar is fixed a roll, upon which the ribbon paffes in its way, to be rolled upons the roller, that turns a little below: 18. The clamps, or pieces of wood, in which the broaches that confine the treadles reft. 19. The treadles are long narrow pieces of wood, to the ends of which the cords that move the liffes are faftened. 20. The trcadle-cords are only diftinguifhed from the riding-cords by a board full of holes, which divide them, in order to prevent the plate-leads, which are tied to the high-lifies, from pulling them too high when the workman's foot is off the treadle: which itop is made by a knot in the treadle-cord, too big to be forced througli that hole in the board. 21. The lams are two pieces of thin narrow boards, only ufed in plain works, and then to fupply the place of the long-harnefs. 22. The knee-roll, by which the weaver rolls up his ribbon as he fees proper, or by bit and bit as it is finihed. 23. The back-rolls, on which the warp is rolled. It is to be obferved, that there is always as many rolls as colours in the work to be wove. 24. The clamps, which fupport the rallers. 25. The returnin \(\alpha\)-ficks, or, as others call them, the returns, or the tumblers, or pulleys, to which the tiers are tied, to clear the courfe of cords through the high-liffes: 26. The catch-board for the tumblers. 27. The tirc-board. 28. The buttons for the knee-rolls and treadle-board, defrribed in \(\mathrm{N}^{\circ} 20\).

It is fated in the proceedings of the National Infitute of France, that a report was prefented to that body concerning a new machine for weaving ribbed nockings. The advantages which this machine poffellics are faid to be, that it may be erected at one-half of the expence of the Englifh focking frame, and that its movernents are much lighter. The experience of its operations for two years has confirmed thefe advantages. Of the nature and conftruction of this machinc we have had no opportunity of obtaining any information ; but we thought it worth while to infert this thort notice, with the view of directing the attention of fuch of our readers as may be interefted in the improvemeres of fuch manufactures.

WEE, a fort of tiffuc or texture formed of threads interwoven with each other; fome whereof are extended in length, and called the warp; others asc arawn acrofs, and called the woof.

WEBERA, a genus of plants belonging to the clafs and order pentandria monogynia. See Lozany Inder.

WEBSTER, Alexander, D.D. was the fon of James Webfter, miniter of the Tolbooth church in Edinburgh, and born in that city about the year \(170 \%\). He was only 13 ycars of age at the death of his father, and of courfe could derive little from parental infruction or example. He fludied at the univerfity of Edinburgh the feveral branches of learning with great approbation,

guikied from the lefs illuttrious dead. No monumental Itone marks the place of their duf.

Nature endowed Dr Webfter with frong facultics, which werc afterwards improved by a conliderable thare of erudition. He was a mafter in the knowledge of the world and of human nature ; his addrels was engaging; his wit Arong as lis mind; his convivisl powers, as they are called, enchanting. Ite had a conllitunional lrength againt intoxication, whel made it dangerous in noft men to attempt bringing lim into fuch a fate. His claracter as a minitler was popular in the extieme. His voice was harmonious, and his figure noble. "Io the poor he was a father and a friend, a liberal patron to poor thudents. In his peifon he was tall, and of a thin and meagre habit. His features were itrongly marked, and the conformity of the whole indicated genius and independence.

To him the widows of the clergy are indebted for the eflablinment of the celebrated Scheme, the plan of which he matured in lis mind foon after be was appointed a minitter of the lolbooth church. By it the widows of minifters are entitled to the annual fum of 10 , 15,20 , or 25 pounds, according as the clergy pay into the fund yearly, 2l. 12s. 6d.-3l. 18s. 9d.-5l. 5 s or 61. 11 s .3 d , or to their children in fums of \(100-\) \(150-200\)-or \(25=1\), in favour of which an act of parliament was obtained in terms of a petition ( 17 Geo . 11.) with liberty to employ the furplus of the annual payments and expences in juans of 301 . each among the contributors, and to put ont the remainder at interen, on proper fecurity. A. fecond act was procured in the 22d year of the fame reign ( 1748 ) granting liberty to raife the capital to 80,0001 , including the fums lent to contributors. The fund is conccived to commence from the 25th March 1744. 'Ihis was followed by another act in the year 1770 , difcontinuing the loan granted to contributors, and granting liberty to raife the capital to 100,0001 .; and the whole economy of the inftitution was then fixed and determined, a report of the llate of the fund being ordered to be made annually to the General Affembly by the truftees, which was to be afierwards printed. The fuccefs of the fcheme has been complete.

WEDGE, one of the mechanical powers. See MEChanics.

WEDNESDAY, the fourth day of the week, fo called from a Saxon idol named Woden, fuppofed to be Mats, worlhipped on this day.

A/b-WEDNESDAE, the firt day of Lent, fo called from the culom oblerved in the ancient Chrinian church. of penitents expreffing their humiliation at this time, by appearing in fack-cloth and athes.

WEED, a common name for all rank and wild herbs, that grow of themfelves, to the detriment of other ufeful herbs they grow among.

WEED; in the miners language, denotes the degeneracy of a load or vein of fine metal into an ufele§s marcalite.

Weeds, alfo denote a peculiar habit, worn by the relicts of nerfons deceafed, by way of mourning.

WEEK, in chronology, a divifion of time comprifing. feven days. Sce Planetart Days and Sabbath.

Paflion-WEEK, or the Holy WEEK, is the laf week in Lent, wherein the church celebrates the myflery of, our Savious's death and palion. .

\section*{W E I}

Feaft of LTEEKs. See Pentecost.
Weever. See Trachinus, Ichthyology Inden. WEEVIL, in Zoolgy, a fpecies of curculio. See Curculio, Entomology Index; and for the method of deltroying this troublefome and deftructive infect, fee Granary and Vermin.

VEIGELIA, a genus of plants belonging to the clafs and order pentandria monogynia. See Botany Index.

WEIGH, a weight of cheefe, wool, \&c. containing \(=56\) pounds avoirdupois. Of corn, the weigh contains 40 buthels; of barley or malt, fix quarters. In fome places, as Eflex, the weigh of cheefe is 300 pounds.

WEIGHING, the aet of examining a body in the balance to find its weight.

WEIGHING Anchor, is the drawing it out of the ground it had been caff into, in order to fet fail, or quit a port, road, or the like.

WEIGHT, in Phyfics, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined in a lefs limited manner, to be a power inherent in all bodies whereby they tend to fome common point, called the centre of gravi\(y\), or, to fpeak more accurately, to one another : and that with a greater or lefs velocity, as they are more or lefs denfe, or as the medium they pafs through is more or lefs rare. See Mechanics.

Weight, in commerce, denotes a body of a known weight appointed to be put in the balance againf other bodies whofe weight is required.

The fecurity of commerce depending, in a good meafure, on the juftnefs of weights, which are ufually of lead, iron, or brafs, moft nations have taken care to prevent the falfification thereof, by flamping or marking them by proper officers, after being adjufted by fome original ftandard. Thus, in England, the ftandard of weights is kept in the exchequer by a particular officer, called the clerk of the market.

Weights may be diftinguifhed into ancient and modern.

\section*{I. Ancient Weights.}
1. Thole of the ancient Jews, reduced to the Englifh troy weight, will fand as in the following table:

2. Roman weights, reduced to Englifh troy weight, will fand as is in the following table:

The Roman ounce is the Englifh avoirdupois ounce, which they divided into feven denarii, as well as eight drachmas.
3. Altic Weights.

Englifh Troy Weight
Drachma ib. oz. dwt. gr.

\section*{II. Modern Weights.}
1. Englihl Weights.-Mr Renardfon, in a paper pub. lithed in the Philofophical Tranfactions, has proved, that at firft there was but one weight in England, and that this was the avoirdupois. Troy weight was introduced in the time of Henry VII.: At prefent, both the troy and avoirdupois weights are ufed in England. Troy weight feems to have derived its name from Troyes, a town in France, where a celebrated fair was kept. It is ufed for weighing gold, filver, jewels, filk, and all liquors. The avoirdupois is ufed for weighing other things.

Table of Troy Weight, as ufed by the

\section*{Goldfmiths, d.c.}

Grains.

The troy pound in Scotland, which by fatute is to be the fame as the Frencli pound, is commonly furpofed equal

Weight. equal to 15 ounces and three quarters troy Englifh weight, or 7560 grains. But by a mean of the flandards kept by the dean-of-guild of Edinburgh, it weighs \(7599 \mathrm{~T}^{\frac{2}{2}}\) or 7600 grains.

\section*{TABLE of Avoirdupois Weight.}

The avoirdupois pound is equal to 7004 troy grains, the avoirdupois ounce to 437.75 grains; and it follows of confequence, that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107, fo is 5760 to 7003.636 : that the troy ounce is to the avoirdupois ounce as 80 to .73 nearly; for as 80 to 73 , fo is 480 to 438 . An avoirdupois pound is equal to Ilb . 202 . IIdwts. 20 gr . troy; a troy ource is equal to 1 oz . 1.55dr. avoirdupois; an avoirdupois dram contains 27.34375. grains; 175 troy pounds are equal to 144 avoirdupois pounds.

The moneyers have a peculiar fubdivifion of the grain troy: thus,
\[
\text { The }\left\{\begin{array}{l}
\text { Grain } \\
\text { Mite } \\
\text { Droit } \\
\text { Periot }
\end{array}\right\} \text { into } \begin{cases}20 & \text { Mites, } \\
24 & \text { Droits. } \\
20 & \text { Periots. } \\
24 & \text { Blanks. }\end{cases}
\]

The Engliih weights are ufed in the United Provinces of America.
2. French Weights.-Different weights were formerly ufed in moft of the different provinces of France: Thefe, however, have undergone very material alterations finee the revolution in that kingdom. See MeaSURE. But as a knowledge of the ancient weights of that country is of importance, on account of the books in which they are ufed, we infert the following tables. The Paris pound contains 16 ounces, and is divided two ways.

Grains.

Vol. XX. Part II.

The weights of the firt divifion are ufed to weigh, gold, filver, and the richer commodities; and the weights of the fecond divifion for commodities of lefs value.
The Paris 2 marc, or pound weight, is equal to 7563 grains troy, and the Paris ounce equal to 472.5 grains troy.
\begin{tabular}{l} 
The Paris pound \(=1 \begin{array}{lllll}\text { 1t. oz. dwt. gr. } \\
1 & 3 & 15 & 0 & \text { troy. }\end{array}\) \\
The Paris ounce \(=0\) \\
\hline
\end{tabular}
A grain troy \(=1.2186507\) of a Paris grain.
But the pound was not the fame throughout Frince. At Lyons, \(e, g r\). the city pound was only 14 ounces: fo that 100 Lyons pounds, made only 86 Paris pounds. But befide the city pound, they had another at Lyons for filk, containing 15 ounces. At Thouloufe, and throughout the Upper Languedoc, the pound was 13 ounces and a half of Paris weight. At Marfeilles, and throughout Provence, the pound was I \(3 \frac{?}{\frac{2}{2}}\) ounces of Paris weight. At Rouen, befide the common Paris pound and marc, they had the weight of the vicomte; which was 16 ounces, a half, and five-fixths of the Paris weight. The weights enumerated under the two articles of Engliih and French weights are the fame that are ufed throaghout the greateft part of Europe; only under fomewhat different names, divifions, and proportions.

French weights were formerly ufed in all the French American fettlements.
3. Dutch Weights.-The weight ufed in Amfterdam and all over Holland is called Troy weight, and is exactly the fame with that ufed at Brufels. The Dutch weights are as follows:

\section*{Deukens.}
\begin{tabular}{|c|c|c|c|c|c|}
\hline 2 & \multicolumn{5}{|l|}{Troyken.} \\
\hline 4 & 2 & Vierling & & & \\
\hline 16 & 8 & 4 & As. & & \\
\hline 512 & 256 & 128 & 32 & Angle & \\
\hline 10240 & 5120 & 2560 & 640 & 20 & Ounce. \\
\hline 81920 & 40960 & 20480 & 5120 & 160 & \\
\hline
\end{tabular}

The marc is equal, aecording to M . Tillet, to 4620 French grains.
\[
4 S
\]

The

Weight. The Amfterdam pound ufed in commerce is divided into 16 ounces, 32 loots, or r 28 drams. This pound contains 2 marcs troy, and ought therefore to weigh only 10240 as: but it weighs 10280 ; fo that it is a little heavier than the troy pound of Amiterdam: 2561 b . of commerce are equal to 257 lb . troy of Holland. Two different pounds are ufed by apothecaries; the one containing 2 marcs, the other only \(1 \frac{7}{\frac{7}{2}}\). The firt is called arfenic pound weight; it contains 16 ounces, the ounce 8 drams, the dram 8 fcruples, the fcruple 20 grains. The fecond is called the apothscary's pound; it is divided into 12 ounces, or 24 loots. Three arfenic pounds are equal to 4 apothecary's pounds.

The Dutch ftone - \(=8\) commercial lb .
The Lifpundt, or L1. \(={ }^{15}\)
The hundred weight \(=100\)
The Schippondt, or Sch. lb. \(=300\)
4. Spani/b Weights.-The mare of Caftile, ufed for weighing gold and filver, is divided as follows:

Grains (gold weight).

The marc, according to Tillet, is equal to 7 oz . 4 gros, 8 grains French, which is equal to 4785 as of Holland. One lhundred marcs of Catile \(=\) about \(93 \frac{1}{2}\) marcs of Holland ; 100 marcs of Holland \(=107\) marcs of Caftile. Medicines are fold by the fame marc; but it is divided differently, containing 8 ounces, 6 drachms, 192 fcruples, \(38+\) obolos, 1152 caracteras, 4608 grains.

The Spanifh commercial pound is divided into two marcs, called marcs of Tejo, each of which is equal to the marc of Caftile. This pound is divided into 16 ounces, 256 adarmes, 9,216 grains.
5. Weights of Portugal.- The Libon marc for effaying filver coin of 12 deniers, and the denier of 24 graius. The marc of Portugal for weighing gold and filver is equal, according to Tillet, to 7 ounces \(3^{\frac{1}{2}}\) gros, and 34 grains French; which makes 4776 a.s of Holland; fo that it is exactly the fame with the Lifbon pound. It is divided into 8 ounces, 64 outavas, 192 fcruples, 4608 grains.

The pound confifts of 2 marcs, 16 ounces, or 96 outavas ; the arroba of 32 lb . ; the quintal of 4 arrobas, or 128 lb . 100 Oporto pounds make \(87 \frac{\gamma}{\sigma}\) th pounds of commerce of \(A\) miferdam.
6. Weighes of tialy,-Ginoa. Two kinds of weights
are ufed at Genoa, the pefo grofo (heavy weight), and Weight. the pefo fottile (light weight) : the latter is ufed for weighing gold and filver, the former for other things. The pound of the pefo fottile is equal, according to Tillet, to 1 marc, 2 ounces, \(2 \frac{1}{\frac{1}{2}}\) gros, 30 grains French. It is divided into 8 ounces, the ounce into 24 deriers, and the denier into 24 grains. The pound of the pefo grofo is equal to I marc, 2 ounces, 3 gros, 5 grains, French It is divided into 12 ounces :
\(\begin{aligned} \text { The cantaro } & =100 \mathrm{lbs} \text {. pefo groffo. } \\ \text { The rubbo } & =25 \mathrm{lbs} \text {. } \\ \text { The rotolo } & =1 \frac{T}{3} \mathrm{lb} .\end{aligned}\)
100 lbs. pefo groffo \(=64 \frac{9}{3} 1 \mathrm{lb}\). of commerce of Amiterdam. 100 lbs . pefo fottile \(=129\) marcs troy of Holland.

Rome. The Roman pound confilts of 12 ounces, the oance of 24 deniers, the denier of 24 grains. The Roman pound, according to Tillet, is equal to 1 marc, 3 ounces, \({ }^{\frac{x}{2}}\) gros, 14 grains, French.

Venice. The marc for weighing gold and filver contains 8 oances, 32 quarti, 1152 carati, or 4608 grani. An hundred mares of Venice \(=97^{\frac{1}{3}}\) marcs troy of Holland, 100 marcs of Holland \(=103\) of Venice. In Venice they alfo ufe a pefo grofo and pefo fottile. 100 lbs . pefo grofo \(=94 \frac{4}{5}\) commercial lbs. of Amferdam. 100 lbs . pefo fottile \(=61 \frac{2}{7}\) ditto.
7. Swedifb Weights. - The mare for weighing gold and filver is equal to 16 lods, 64 quentins, or \(43^{8} 4\) as. The pound of 32 lods, ufed for weighing food, is equal, according to Tillet, to 1 marc, 5 ounces, 7 gros, 8 grains French, which makes \(8848 \frac{5}{\frac{5}{2}}\) as troy of Holland. This anfwers exactly to the weight of the different pounds, as fixed in Sweden, viz. \(88_{4} 8\) as \(=\) the pound for weighing articles of food; \(7821{ }^{-90}\) as \(=\) marc ufed in the mines; \(7450 \frac{2}{43}\) as \(=\) marc ufed in towns and in the country; \(7078 \frac{3}{5}\) as \(=\) marc ufed for weigh. ing inon; 7416 as \(=\) pound ufed in medicine.
```

The flippund $=400 \mathrm{lbs}$. for weighing food,
The centner $=120 \mathrm{lbs}$.
The waag $=165 \mathrm{lbs}$ 。
The ften $=32$ lbs.
The Stredifh as $=1$ as of Holland troy.

```
8. German Weights.-Vienna. The marc of Vienna for weighing gold and filver is divided into 16 loths, 64 quintals, or 256 deniers or pfenings; the loth into 4 quintals, or 16 pfenings- This marc, according to Tillet, is equal to 1 marc, 1 ounce, 1 gros, 16 grains, French, \(=5831\) as troy Holland. The pound of Vienna is divided into 2 marcs, or 4 viertings; the mark into 8 ounces, 16 luths, 64 quintals, or 266 pfenings.

Hamburgh. The marc for effaying gold is divided into 24 carats; the carat into 12 grains. The marc for filver is divided into 16 loths, and the loth into 18 grains. Thefe marss confift each of 288 grains, and are therefore equal. This marc, ufed in Hamburgh for gold and filver, is the mare of Cologne, which is equal, according to Tillet, to 7 ounces, 5 gros, \(7 \frac{3}{3}\) grains, French, \(=4866\) as troy of Holland. It is divided into 8 ounces, 16 loths, 64 quentins, \(25^{5}\) pfenings, 4352 efches, or 65536 richt pfeniugs thcile. The apothecary pound ufed in Hamburgh, and almot all Germany, is divided into 12 ounces, 96 drachms, 288 fcruplcs, or 5760 grains ; an ounce is cqual to 621 as of Holland.

Weight. The pound of commerce is equal, according to Tillet, to 1008 ; as of Holland ; for half a pound is equal to 7 ounces, 7 gros, 23 grains, French. This pound is divided into 16 ounces, 32 loths, 128 quentins, or 512 pfenings.
9. Ruflıan Weights.-The berckowitz \(=400 \mathrm{lbs}\). The poud \(=40 \mathrm{lbs}\).
The pound is divided into 32 loths, or 96 folotnuks. One hundred Ruffian lbs. \(=166 \frac{2}{2}\) marcs, or \(82{ }_{3}^{4} \mathrm{lbs}\). of Amfterdam. One hundred lbs , of commerce of \(A m f t e r-\) dam \(=120 \frac{3}{4}\) th lbs. of Rullia.
10. Welghts ufed in the feveral parts of Afta, the Eaf Indies, China, Pcr/in, \&c.-In'Turkey, at Smyrna, \&c. they ufe the batman, or battemant, containing \(7 \frac{1}{\frac{1}{Y}}\) occos; the occo contains 4 chekys or pounds, cach of which, according to Tillet, is equal to 1 marc 2 oz .3 gros. 28 gr. French. The Turkifh weights are divided as follows:
\[
\begin{aligned}
& \text { Cantaras. Batmans, Oceos. Rotolos. Chekis, Mefcals. Drachms. } \\
& 1=7 \frac{1}{2}=44=100=176=11733 \frac{1}{3}=17600 \\
& I=6=13 x^{3}=24=1600=2400 \\
& I=2 x^{3} x=4=266 \frac{2}{3}=400 \\
& x=1 \frac{19}{28}=117 \frac{1}{3}=176 \\
& \begin{array}{rlr}
66 \frac{2}{3}= & 100 \\
1 & =1 \frac{1}{2}
\end{array}
\end{aligned}
\]

At Aleppo there are three forts of rottos; the firft 720 drachms, making about 7 pounds Englif, and ferving to weigh cottons, galls, and other large commodities; the fecond is 680 drachms, ufed for all filks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant, not named hacre, ufe come of thefe weights; particularly the occa, or ocqua, the rottoli, and rotto.

The Chinefe weights are, the piece for large commodities: it is divided into 100 catis or cattis, though fome fay into 125 ; the cati into 16 taels or tales, each tael equivalent to \(1 \frac{7}{3}\) of an ounce Englifh, or the weight of one rial and \(\frac{r_{2}}{2}\), and containing 12 mas or maffes, and each mas 10 condrins. So that the Chinefe piece amounts to 137 pounds Englifh avoirdupois, and the cati to \(I\) pound 8 ounces. The picol for filk containing 66 catis and \(\frac{3}{4}\); the bahar, bakaire, or barr, containing 300 calis.

Tonquin has alfo the fame weights, meafures, \&c. as China. Japan has only one weight, viz. the cati; which, however, is different from that of China, as containing 20 taels. At Surat, Agra, and throughout the fates of the Great Mogul, they ufe the man, or maund, whereof they have two kinds; the king's maund, or king's weight ; and the maund fimply; the firt ufed for the weighing of common provifions, containing 40 feers, or ferres; and each feer a jult Paris pound. The common maund, ufed in the weighing of merchandife, contilts like. wife of 40 feers, but each feer is only eflimated at 12 Paris ounces, or \(\frac{3}{4}\) of the other feer.

The maund may be looked upon as the common weight of the Ealt Indies, though under fome difference of name, or rather of pronunciation; it being called mao at Cambaya, and in other places mein and maum. The feer is properly the Indian pound, and of univerfal ufe; the like may be faid of the bahar, tael, and catti, above mentioned.

The weights of Siam are the piece, containing two fhans or cattis; but the Siamefe catti is only half the Japanefe, the latter containing 20 taeis and the former only 10 ; though fome make the Chinefe catti only if taels, and the Siamefe 8. The tael contains 4 bats, or ticals, each about a Paris ounce; the baat 4 felings or mayons; the mayon 2 fouangs; the fouang 4 payes; the paye 2 clams; the fompaye half a fouang.

It is to be obferved, that thefe are the names of their coins as well as weights; filver and gold being commodities there fold, as other things, by their weights.

In the inle of Java, and particularly at Bantam, they ufe the gantan, which amounts to near 3 Dutch pounds. In Golconda, at Vifapour, and Goa, they bave the furatelle, containing I pound it nunces Englifh; the mangalis, or mangelin, for weighing diamonds and precious tlones, weighing at Goa 5 grains, at Golconda, \&c. \(5^{\frac{1}{2}}\) grains. They have allo the rotolo, containing \(14 \frac{\text { T}}{\frac{1}{3}}\) ounces Englith; the metricol, containing the fixth part of an ounce ; the wall for piallres and ducats, containing the 73 d part of a rial.

In Perfia they ufe two kinds of batmans or mans; the one called cahi or cherny which is the king's weight, and the other batman of Tauris. The firl weighs 13 pounds 10 ounces Engliih; the fecond \(6 \frac{1}{2}\) pounds. Its divifions are the ratel, or a 16 th; the derhem, or drachm, which is the 50th; the mefchal, which is half the derhem; the dung, which is the fixth part of the meichal, being equivalent to 6 carat grains; and, laftly, the grain, which is the fourth part of the dung. They have alfo the vakie, which exceeds a little our ounce; the fah-cheray, equal to the II 70 oth part of the derliem; and the toman, ufed to weigh out large payments of money without telling; its weight is that of 50 abaffes.
11. Weights at Cairo in Egypt.-Almoft every kind of goods las its own weight; thefe are regulated by the cantaren or principal weight.

Rotels.
The ordinary cantaren, or hundred weight, weighs 100
The cantaren of quickfilver and tin . 102 coffee, wine, and iron - 105
ivory \(\begin{array}{ll}\text { ivory } \\ \text { almonds and other fruits } & 115\end{array}\) woods for dying - 120 arfenic and other drugs - 125 minium and cinnabar - 130 gurn-arabic, aloes, and other aromatics 133
The ratel or rotoli is nearly equal to the pound of Marfeilles; 108 lbs . of Mareilles are equal to ino rotels. The Marfeilles pound confifts of 13 ounces of Paris; fo that the 100 lbs , of Marfeilles are equal to 8 rlbs . Pais, and 100 lbs . Paris \(=123 \mathrm{lbs}\). of Marfeilles.

We thall fubjoin here Mr Fergufon's table for com. paring the Englifh avoirdupois pound with foreign pounds:

\begin{tabular}{|c|c|c|c|}
\hline & W E & I' & 69 \\
\hline \multirow[t]{9}{*}{\[
\underbrace{\text { Weight. }}
\]} & Genoa, grofs 0.7 & Rochelle & 0.8928 \\

\]

A curious weighing machine was fome time ago invented by M: Hanin of Paris, whereby the weights of the principal countries in Europe, and the relative proportions they bear to each other, are fhown at one view. For this he received a bounty of 20 guineas from the Society inftituted at London for the encouragerment of Arts, Manufactures, and Cormerce. The following is a defcription of this ingenious machine.

Plate
Figure 1. reprefents the back of the machine, which being fufpended by the ring A , and a weight hung to the hook B , the fpring \(\mathrm{C}, \mathrm{C}, \mathrm{C}\), made faft by ftrong fcrews at \(g\), is drawn downwards; and the bar D baving a rack thereon at \(e\), turns the pinion \(f\), in proportion to the weight of the body hanging thereto. Figure 2. fhows the face of the machine, on which is a number of concentric circles, and the weights of feveral countries of Europe engraved thereon, as expreffed by the words on a line with them. In the centre of this face is a ring fixed to the fmall plate, turned by the pinion \(f\), fhown at figure 1 . From this ring a hand projeets, which, by the turning of the pinion, points to fuch part of the circle as is marked with the weight liung to the hook B; and thereby fhows what weight of any of the countries mentioned, is equal to the pounds troy of London, which are engraved on the outer circle, or to the pounds avoirdupois, which are engraved on the fecond circle, and fo of the reft. A flider moves on the land, which may be brought to any of the circles at

\section*{W E I}
pleafure, in order to point out the relative weight, with
Weight. greater precifion.

Many attempts have been made to introduce an uniformity of weights and meafures into the commercial world; but hitherto they have all failed. The accom. plifhment of fuch an undertaking would be of infinite advantage to mankind, and certainly claims the moft ferious attention of thofe who by their fituation can alone bring it about. The undertaking is indeed difficult, but furely not impoffible. Something of this kind has been attempted and adopted in France; and, as the method is fimple, and exceedingly well adapted for calculation, it furely deferves to be imitated. - See Measure.

Weight of Air. See Pneumatics, No 14-19. !
Regulation of WeIGHTS and Meafures, is a branch of the king's prerogative. See Prerogative and Measure.

As weight and meafure are things in their nature arbitrary and uncertain, it is therefore expedient that they, be reduced to fome fixed rule or flandard: which ftandard it is impoffible to fix by any written law or oral proclamation; for no man ean, by words only, give another an adequate idea of a foot rule, or a pound weight. It is therefore neceffary to have recourfe to fome vifible, palpable, material ftandard; by forming a comparifon with which all weights and meafures may be reduced to one uniform fize; and the prerogative of fixing this flandard, our ancient law veited in the crown, as in Normandy it belonged to the duke. This ftandard was originally kept at Winchefter : and we find in the laws of King Edgar, near a century before the conqueft, an injunction that the one meafure, which was kept at Winchelter, fhould be obferved throughout the realm. Moft nations have regulated the Standard of meafures of length by comparifon with the parts of the human body; as the palm, the hand, the fpan, the foot, the cubit, the ell (ulna or arm), the pace, and the fathom. But as thefeare of different dimenfions in men of different proportions, our ancient hiftorians inform us, that a new ftandard of longitudinal meafure was afcertained by King Henry the Firft; who commanded that the ulna, or ancient ell, which anfwers to the modern yard, fhould be: made of the exact length of his own arm. And one ftandard of meafure of length being gained, all others are eafily derived from thence; thole of greater length by multiplying, thofe of lefs by dividing, that original ftandard. Thus, by the ftatute called compofitio wlnarum et perticarum, five yards and a balf make a perch; and the yard is fubdivided into three feet, and each foot into 12 incles; which inches will be each of the length. of three grains of barley. Superficial meafures are derived by fquaring thofe of length; and mealures of capacity by cubing them. The ftandard of weights was originally take from corns of wheat, whence the lowelt. denomination of weights we have is ftill called a grain;: 32 of which are directed, by the flatute called compofirio menfurarum, to compole a pennyweight, wherc of 20 make an ounce, 12 ounce's a pound, and fo upwards. And upon thefe principles the frit ftandards were made; which, being originally fo fixed by the crown, their fubfequent regulations have been generally made by the king in parliament. I hus, under. King hichard I. in his parliament holden at Weftminfter, A. Dál 1197 , it wàa ordained that there hould be only one weight and one

\section*{W E L} meafure throughout the kingdom, and that the cufody
of the aflize, or flandard of weights and meafures, flould be committed to certain perfons in every city and borough'; from whence the ancient office of the king's aulnager feems to have been derived, whofe duty it was, for a certain fee, to meafure all cloths made for fale, till the office was abolifhed by the ftatute 1 th and \(12 \mathrm{th}_{1}\) William III: c. 20. In King John's time this ordinance of King Richard was frequently difpenfed with for money; which occafioned a provifion to be made for enforcing it, in the great charters of King John and his fon. Thefe original fandards were called pondus regis, and menfura domini regis, and are directed by a variety of fubfequent flatutes to be kept in the exchequer chamber, by an officer called the clerk of the market, except the wine gallon, which is committed to the city of London, and kept in Guildhall.

The Scortijb flandards are diftributed among the oldef boroughs. The elwand is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the firlot at Linlithgow.

Various flatutes have been enacted for regulating and enforcing an uniformity of weights and meafures; and by the articles of union, the Englifh flandards are eftablifhed by law over all Great Britain. But the force of cuftom is fo Atrong, that thefe flatutes hare been ill oblerved. The Scottih ftandards are fill univerfally retained for many purpofes; and likewife a variety of local weights and nseafures are ufed in particular places of both countries, which differ from the general flandards of either.

WEINMANNIA, a genus of plants of the clafs oflandria, order monogynia, and arranged in the natural claffification with thofe plants the order of which is doubtful. The calyx is four-leaved, the corolla has four petals, and the capfule is bilocular and biroftrated. There are fix feecies, none of which are natives of Britain.

WELD, or Wold. See Reseda, Botany Indec, and Dyeing.
WELDING heat, in fmithery, a degree of heat given to iron, \&c. fufficient to make the furfaces of two pieces incorporate upon being beaten together with a hammer.

WELL, a hole under ground, ufually of a cylindrical figure, and walled with fone and mortar: its ufe is to collect the water of the ftrata around it.

Well, an apartment formed in the middle of a thip's hold to inclafe the pumps, from the bottom to the lower decks. It is ufed as a barrier to preferve thofe machines from being damaged by the fricion or compreffion of the materials contained in the hold, and particularly to prevent the entrance of ballaft, \&c. by which the tubes would prefently be chocked, and the pumps rendered incapable of fervice. By means of this inclofure, the artificers may likewife more readily defcend into the hold, in order to examine the flate of the pumps, and repair them as occafion requires.

WELL-Room of a Boat, the place in the bottom where the water lies between the ceiling and the platform of the flern-ffeets, whence it is thrown out into the fea with a fcoop.

\section*{Burning-Well. See Burning-Spring.}

Wex'L of a Fi/hing-vefel, an apartment in the middle of the hold, which is entirely detached from the reft, being lined with lenc on every fide; and having the bot-

3 ] W E " P
tom thereof penetrated with a competent number of fmall holes palling alfo through the flip's floor; fo that the falt-water running into the well is always kept a, frefh as that in the fea, and yet prevented from communicating itfelf to the other parts of the hold.

WeI.L-hole, in building, is the hole left in a floor for the ftairs to come up through.

WELLS, a city of Somerfethire, and fee of a bifthop; the bilhop of Bath being alfo that of Wells.-It is fuppofed to take its name from the many fprings and wells that are near it. It is not very large; but is adorned with handfome buildings, both public and private. Its cathedral is a very beautiful ftructure, adorned with images and carved fone work. The bilhop's palace joins to the cathedral; and on the other fide are the houles for the prebendaries. In the market place is a fine market houfe, fupported by pillars. It is goverued by a mayor, and fends two members to parliament. The chief manufacture is knit hofe. W. Long. 2. 37. N. Lat. 51. 12.

WEN, a tumor or excrefcence arifing on different parts of the body, and containing a cyfus or bag filled with fome peculiar kind of matter. See Nevus, Surgery Index.

WEREGILD, the price of homicide; paid partly to the king for the lofs of a fubject, partly to the lord whofe vaffal he was, and partly to the next of kin of the perfon hain.

WERST, WURst, or \(V_{\text {erfl, }}\) a Ruffian meafure equal to 3500 Englifh feet. A degree of a great circle of the earth contains about 104 werffs and a half.

WERTURIAN or Uralian Mountains, a famous clain of mountains forming part of the boundary of \(\Lambda\) fia. It begins difinetly (for it may be traced interuptedly farther fouth) near the town of Kungur, in the government of Kafan, in latitude \(57^{\circ} 20^{\prime}\); runs north, and ends oppofite to the Waygatz Atrait, and rifes again in the ine of Nova Zenlja. The Ruflians allo call this range Semennoi Poias, or, the girdle of the world; frem a fappofirion that it encircled the univerfe. Thefe were the Ripheci montes: Pars mundi damnata a natura rerum, et denfa merfa caligigne \({ }^{*}\); of which only the fouth-* Ptivi ern part was known to the ancients, and that fo little as Hijf. Na\%o to give rife to numberlcfs fables. Beyond thefe were \({ }^{\text {lib. iv. }}\) placed the happy Hyperborci, a fiction molt beautifully \({ }^{\text {cap. }}\).3. related by Ponpponius Mela, Moderns have not been behind-hand in exaggerating feveral circumflances relative to thefe noted bills. Ybrand Ides, who crofled them in his embafly to China, afferts that they are 5000 toifes or fathoms high; others, that they are covcred with eternal fnow. The laft may be true in their more nothern parts; but in the ufual paffages over them, they are free from it three or four months.
The heights of part of this chain have been taken by M. l'Abbé d'Auteroche: who, with many affurances of his accuracy, fays, that the height of the mountain Kyria near Solikam@aia, in latitude \(60^{\circ}\), does not exceed 47 I toifes from the level of the fea, or 286 from. the ground on which it ftands. But, according to M. Gmelin, the mountain Pauda is much higher, being 752 toifes above the fea. From Peterßurgh to this chain is a vaf plain, mixed with certain elevations or platforms, like iflands in the midnt of an ocean. The eaftern fide defcends gradually to a great diftance intathe wooded and morafly; Siberia, which Forms'an inm.

Werturian, menfe inclined plane to the Icy fea. This is evident Wefley: from all the great aivers taking their rife on that fide,
fome at the amazing diftance of latiunde \(46^{\circ}\); and, after a courfe of above 27 degrees, falling into the Frozell ocean, in latitude \(73^{\circ} 30^{\prime}\). The Yalik alone, which rifes near the fouthern part of the eattern fide, takes a fouthern direction, and drops into the Cafpian fea. The Dwina, the Peczora, and a few other rivers in European Ruffia, thew the inclined plane of that part. All of them run to the northern fea; but their courfe is comparatively thort. Another inclination direets the Dnieper and the Don into the Eaxine, and the valt Wolga into the Cafpian fea.

WESLEY, John, a very extraordinary character, and founder of the fect of Methodifts, was the fon of the Reverend Samuel Welley, rector of Epworth in the ifle of Axholme in Lincolnfiire, and was born in that village in the year 1703 . His very infancy was difringuifhed by an extraordinary incident; for when he was only fix years old, the parfonage-houfe at Epworth was burnt to the ground, and the flames had fpread with fuch rapidity, that few things of value could be faved. His mother, in a letter to her fon Samuel Weney, then on the foundation at Weffminfter fchool, thanks God that no lives were loft, although for fome time they gave up Poor Jacky, as the exprefles herfelf; for his father had twice attempted to refcue the child, but was beaten back by the tlames. Finding all his efforts ineffectual, he refigned him to Divine Providence. But parental tendernefs prevailed over human fears, and \(\mathrm{Mr}_{r}\) Weficy once more attempted to fave his child. By fome means equally unexpected and unaccountable, the boy got round to a window in the front of the houfe, and was taken out, by one man's leaping on the fhoulders of another, and thus getting within his reach. Immediately on his refcue from this very perilous fituation, the roof fell in. This extraordinary efcape explains a certain device, in a print of Mr John Wefley, engraved by Vertue, in the year 1745 , from a painting by Williams. It reprefents a houfe in tlames, with this motto from the prophet, "Is he not a brand plucked out of the burning ?" Many have fuppofed this device to be merely emblematical of his fpiritual deliverance; but from this circumitance it is apparent that it has a primary as well as a fecondary meaning; it is real as well as allufive.

In the year 1713 he was entered a fcholar at the charter-houfe in London, where he continued feven years under the tuition of the celebrated Dr Walker, and of the Rev. Andrew Tooke author of The Pantheon. Being elected to Lincoln college, Oxford, he became a fellow of that college about the year 1725 , took the degree of Mafter of Arts in 1726, and was joint tutor with the Rev. Dr Hutchins the reCtor. He difcovered very early an elegant turn for poetry. Some of his gayer poetical effufions are proofs of a lively fancy and a fine clafical tafte; and fome tranflations from the Latin poets, while at college, are allowed to have great merit. He had early a flrongi mpreffion, like Count Zinzendorf, of his defignation to fome-extraordinary woik. This impreffion received additional force from fome domeftic incidents; all which his active fancy turned to his own account. His wonderful prefervation, already noticed, naturally tended to cherin the idea of lis being defigned by Providence to accomplifin fome purpofe or other, that was out of the ordinary courfe of human cevents. The late Rev. Samuel Badcock, in a
letter inferted in the Bibliotheca Topographica Britannica, \(N^{0}\) XX. fays, "There were fome ftrange phenomena perceived at the parfonage at Epworth, and fome uncommon noifes heard there from tinc to time, which he was very curious in examining into, and very particular in relating. I have little doubt that he confidered himielf the chief object of this wonderful vifitation. In deed his father's credulity was in fome degree affected by it; fince he collected all the evidences that tended to confirm the ftory, arranged them with forupulous exactnefs, in a manulcript conffifing of feveral theets, and which is fill in being. I know not what became of the ghot of Epworth; unlefs, confidered as the prelude to the noife of Mr John Wefley made on a more ample Hage, it ceafed to fpeak when he began to act."
"The dawn of Mr Wefley's public miffion (continues Mr Badcock) was clouded with myfticifm; that fpecies of it which affects filence and folitude; a certain inexplicable introverfion of the mind, which abftracts the paflions from all ferfible objects; and, as the French Quietits exprefs it, pelfects itfelf by an ablorption of the will and intellect, and all the faculties, into the Deity." In this palpable obfcure the excellent Fenelon led himfelf, when he forfook the thades of Pindus, to wander in queft of pure looe with Madam Guyon! Mr Wefley purfued for a while the fame ignis fatuus with Mr William Law and the Ghoft of De Renty. A flate, however, fo torpid and ignoble, ill-fuited the active genius of this fingular man. His elaftic mind gained Atrength by comprefion; thence burfting glorious, he paffed (as he himfelf fomewhere fays) "the immenfe chafm, upborne on an eagle's wings."

The reading of the writings of this Mr William Law, the celebrated author of Chriftian Perfection, and of A Serious Addrefs to the Chriftian World, contributed moreover, to lead Mr John Wefiey and his brother Charles, with a few of their young fellow-fludents, into a more than common ftrictnefs of religious life. They received the facrament of the Lord's Supper every week; obferved all the fafts of the church; vifited the prifnns; rofe at four in the morning; and refrained from all amufements. From the exact method in which they difpofed of every hour, they acquired the appellation of Methodijfs; by which their followers have been ever fince dillinguifhed.

But a more particular account of the origin of this Fect, we fhall give from a celebrated publication. "The Methodifs (fays the editor of this work) form a very confiderable clafs, principaly of the lower people in this country. They fprung up about fifty years ago at Oxford, and were foon divided into two partics; the one under the direction of Mr George Whitcfeld, and the other under that of two brothers, John and Charles Wefley. Thefe leaders, and, if we except Mr Williann Law, founders of the Methodifts, were educated at Oxford, received epifcopal ordination, and always profeffed themfelves advocates for the articles and liturgy of the eftablifted church; though they more commonly practifed the diffenting mode of worhip. But conceiving a defign of forming feparate communities, fuperior in fanclity and perfection to all other Chriftian churches, and impreffed to a very confiderable degree by a zeal of an extravagant and enthufiaflic kind, they became itinerant preachers; and, being excluded from moft of our churches, exercifed their miniftry in private houfes,
felds,

Welley. fields, \&cc. not only in Great Britain and Ireland, hut alfo in America; thus collecting a very confiderable number of hearers and profelytes, both among the members of the eflablifhed church and the diffenters. The theological fyftem of Mr Whiteficld and his followers is Calvinillic ; that of Mr Welley and his difciples Armiuian ; and the latter maintains the poffibility of attain. ing finlefs perfection in the prefent thate. The fubordinate teachers of both thefe claffes of Methoditts are generally men of no liberal education; and they pretend to derive their minifterial abilities from fipecial communications of the Spirit. The Methodifls of both parties, like other enthuliafts, make true religion to confift principally in certain affections and invard feelings which it is impoflible to explain; but which, when analyfed, feem to be mechanical in their \(f_{j}\) ring and operation; and they generally maintain, that Chriftians will be mofl likely to fucceed in the purfuit of truth, not by the dietates of reafon, or the aids of learning, but by laying their minds open to the direction and influence of divine illumination; and their conduct has heen direeted by impulfes."

Our readers will judge for themfelves, according to their various modes of education, and to the different lights in which they may refpectively view the doctrines of our common Chrinianity, whether this reprefentation of the origin of the Methodifts, and of their diftinguighing tenets, be accurate and jull. - Not prefuming to fit in judgement on the religious opinions of any man, we thall only obicrve, that an appellation originally given in reproach, has been gloried in ever fince by thofe who have diftinguifhed themfelves as the followers either of Mr Whitefield or of Mr Wefley. "After the way called Methodifm, fo worfhip they the God of their fathers." But the ridicule and contempt which the fingularity of their conduct produced, both John and Charles Wefley were well qualified to bear. They were not to be intimidated by danger, actuated by intereft, or deterred by difgrace.

The boundaries of this illand were fcon deemed by Mr Wefley too confined for a zeal which difplayed the piety of an apofle, and of an intrepidity to which few mifionaries had been fuperior. In 1735 he embarked for Georgia, one of our colonies, which was at that time in a flate of political infancy; and the great object of this voyage was to preach the gofpel to the Indian nations in the vicinity of that province. He returned to England in 1737. Of his fpiritual labours, both in this country and in America, he himfelf has given a very copious account, in a feries of Journals printed at different periods. Thefe journals drew upon our laborious preacher and his coadjutors fome fevere animadverfions from two right reverend prelates; Dr George Lavington bilhop of Exeter, and \(\mathrm{Dr}_{\mathrm{r}}\) William Warburton bifhop of Gloucelier. The former publifhed, in three parts, The Enthufiafm of the Methodits and Papits compared; the third part of this performance containing a perfonal charge of immoral conduct. Mr Welley, in his vindication, publifhed a letter to lis lorddlip, which produced a reply from the latter.

Bilhop Warburton's attack is contained in his celebrated treatife, entitled The Doctrine of Grace: or, The Office and Operations of the Holy Spirit vindicated from the Infults of Infidelity, and the Abufes of Fanaticifm : concluding with fome thoughts, humbly of-
fered to the confideration of the Eflablithed Clergy, Wescy. with regard to the Kight Method of defending Religion againd the Attacks of either party; 2 vols. fmall \(8 \mathrm{vo}, 1762\). There is much acute reafoning, and much poignant and fprightly wit, in his Doctrine of Grace; but there is too mucls levity in it for a grave bifhop, and too much abufe for a candid Chrillian. On this oceafion, Mr Wefley publifited a letter to the bifhop, in which, with great temper and moderation, as well as with great ingemuity and addrefs, he endeavosred to atelter himfelf from his lordhip's attacks; not only under the authority of the Holy Scriptures, but of the church itfelf, as by law effablifhed.

On his return from Georgia, Mr Wefley paid a vifit to Count Zinzendorf, the celebrated founder of the fe \(\varepsilon^{2}\) of Moravians, or Hernhutters, at Hernlut in Upper Lufatia. In the following year he appeared again in England, and with his brother Charles, at the head of the Methoditls. He preached his firlt feld-fermon at Briftol, on the 2d of April 1738 , from which time his difciples have continued to increafe. In 1741 , a ferious altercation took place between him and Mr Whitefield. In 1744, attempting to preach at an inn at Taunton, he was regularly filenced by the magiftrates. Although he chiefly refided for the remainder of his life in the metropolis, he occafionally travelled through every part of Great Britain and Ircland, eflablifhing congregations in each kingdom. In 1750 he married a lady, from whom ine was afterwards feparated. By this lady, who died in r781, he had no children.

We have already mentioned Mr Wenley as a very warious and voluminous writer. Divinity, ooth devotional and controverfial, biography, hiftory, philolophy, politics, and poctry, were all, at different times, the fubjects of his pen : and, whatever opinion may be entertained of his theological fentiments, it is impoffible to deny him the merit of having-done ve:y extenfive good among the lower clafles of people. He certainly poffersed great abilities, and a fluency which was well accom. modated to his hearers, and highly acceptable to them. He had bcen gradually declining for three years before his death ; yet he fill rofe at four in the morning, and preached, and travelled, and wrote as ufual. He preach. ed at Leatherhead, in Surrey, on the Wednefday before that event. On the Friday following, appeared the firts fymptoms of his approaching dififlution. The four fucceeding days he fpert in praifing God; and he left this fcene, in which his labours had been fo extenfive and fo ufeful, at a quarter before ten in the morning of the 2d of March 1791, in the 88th year of his age. His remains, after lying in a kind of flate at his chapel in the city-road, dreffed in the facerdotal robes which he ufitally wore, and on his head the old clerical cap, a bible in one hand, and a white handkerchief in the other, were, agreeably to his own directions, and after the manner of the interment of the late Mr Whitefield, depofited in the cemetry behind his chapel, on the morning of the gth March, amid an innumerable concourfe of his friends and admirers; many of whom appeared in deep mourning on the occafion. One fingularity was obfervable in the funeral fervice. Inflead of, "We give thee hearty thanks, for that it hath pleafed thee to deliver this our brother;" it was read "our father." A fermon, previoufly to the funeral, had been preached by Dr Thomas Whitehead, one of the phyficians to the

Weney, London hofpital; and on the \(13^{\text {th }}\) the different chapels Wett. of his perfuation in L.ondon were hung with black.

It has been jufly obferved of Mr Welley, that his labours were principally devoted to thofe who had no intructor; to the highways and hedges; to the miners in Cornsall, and the coalliers in Kingfivood. Thefe unhappy creatures married and buried among themfelves, and often committed murders with impunity, before the Methodifts fprung up. By the humane and active endeavours of Mr Wefley and his brother Charles, a fenfe of decency, morals, and religion, was introduced into the lowett claffes of mankind; the ignorant were inflructed, the wretched relieved, and the abandoned reclaimed. His perfonal influence was greater, perhaps, than that of any other private gentleman in any coun-try.-But the limits of this article will not permit us to expatiate further on the character of this extraordinary man.

WEST, Gilbert, was the fon of Dr Weft, prebendary of Winchefter, and chaplain to King George I. but at 12 years of age loft his father. He ftudied at Winchefter and Eton Chools, and from thence was placed in Chritt-church college, Oxford. His ftudious and ferious turn inclined him to take orders; but Lord Cobham, his uncle, diverted him from that purfuit, and gave him a cornetcy in his own regiment. This profeffion he foon quitted, on account of an opening of another nature, which prefented him with a flattering profpect of advancement in life. A number of young gentlemen were to be elected from the univerfities, and, at the expence of government, were to be taught foreign languages; and then fent to the fecretaries office, to be initiated into bufinefs, and trained there for public fervices, as envoys, ambaffadors, \&c. Mr Gilbert Weit was one of the few pitched upon; and on his firt introduction into that office, Lord Townfend, fecretary of ftate, treated him with fingular marks of regard, and the firongeft inclinations to ferve him were teflified from all quarters. But his uncle Lord Cobham's flrong oppofition to the meafures of the government, rendered thele advantages entirely fruitlefs; and the minifters honeftly told Mr Weft, that he muft not expect them to diftinguifh his merit, as any favours conferred upon him would be imputed as done to his ancle Lord Cobham. Mr Weft now left that office, and all his views of making his fortune; and entering into marriage, retired to Wickham in Kent, where he lived in great domeftic comfort and tranquil happinefs. He was there vifited by his valuable friends, who held the moft delightful converfe of wit, humour, and learning, fupported upon the principles of virtue, found reafoning, and folid friendmip, which rendered the whole cheerful, animating, and inflructive. Mr William Pitt, who was one of thofe that compofed this happy fociety, becoming paymater, appointed Mr Well treafurer to Chelfea-hofpital; and he obtained a feat at the council-board, in confequence of a friendthip contracted at the fchool with one of the duke of Devonfhire's fons, who procured of his grace his being nominated one of the clerks extraordinary of that office. Towards the latter part of Mr Wen's life, he wholly applied himfelf to the fludy of the Scriptures; being extremely anxious to try his utmoff endeavours to reconcile the fceming inconfiftencies which gave the enemies to revealed religion a handle to doubt and difcredit their authenticity. His obfervations on the re-
furrection, which, it has been haid, were written to confirm the waveing faith of his great friends Pitt and Lyttleton, bear ample teftimony to his reafoning powers and the fincerity of his eligion; while his tranflations of Pindar thow him to have been an eminent Greek fcholar, and very confiderable poet. He had a mind replete with virtue, and was an honour to his country; but died at 50 years of age.

West, one of the cardinal points of the horizon, dizmetrically oppofite to the eaft; and frictly defined the interfection of the prime vertical with the horizon on that fide the fun fets in.

WESTMINSTER, a city which forms the weft part of the capital of Britain, but has a government diflinet from the reff. This city had its name from the fituation of its abbey, anciently called a minfler, in refpect of that of St Paul. That part properly called the city of Weltminfter, comprehending the parifhes of St John and St Margaret, was once an illand formed by the Thames, called Thorney illand, from the thorns with which it was overrun; and the abbey that flood in it, Thorney-abbey. The liberties of Weftminfter contain the feveral parifhes of St Martin in the Fields, St James's, St Anne, St Paul, Covent-Garden, St Mary le Strand, St Clement Danes, St George, Hanover Square, and the precinet of the Savoy. The government, both of the city and liberties, is under the jurifdiction of the dean and chapter of Weftmintter, in civil as well as eccle. fiaftical affairs; and their authority extends to the precinct of St Martin le Grand, by Newgate-ftreet, and in fome towns of Eflex, which are exempted from the jurifdiction of the bifhop of London and the archbihop of Canterbury; but the management of the civil part has, ever fince the lieformation, been in the hands of laymen, elected from time to time, and confirmed by the dean and chapter. The chief of thefe laymen are the highfteward, the depaty-fteward, and the high-bailiff, who hold their offices for life. There are allo a 6 burgeffes and their affiltants, out of which are elected two headburgeffes, one for the city, and the other for the liberties. Another officer is the high-confable, who has all the other conftables under his direction.

IVESTMOREL AND, a county of England, bounded on the north and north-weft by Cumberland; on the fouth and fouth-eaf by Yorkfhire ; and on the fouth and fouth-wer by Lancaflire. Its extent from northeaft to fouth, is 40 miles, and its breadth from the eaft projection to that in the weft, 42. It is generally divided into the baronies of Kendal and Weftmoreland: the former is very mountainous, but the latter is a large champaign country. Thefe are the only principal divifions of this county, which contains eight market towns, 26 parihes, and 41,617 inhabitants. It lies partly in the diocefe of Chefter, and partly in that of Carlife. The earl of Thanet is hereditary fheriff of the county, which fends only four members to parliament. The air is clear, flarp, and falubrious, the natives being feldom troubled with difeafes, and generally living to old age. The foil is various; that on the mountains is very barren, while that in the valleys is fertile, producing good corn and grafs, efpecially in the meadows near the rivers. In the hilly parts on the weflern borders it is generally believed there are vait quantities of copper ore, and veins of gold; fome mines of copper are worked, but moft of the ore lies fo deep that it will not anfwer

\section*{W E T [ 697 ] W H A}

Tofmare- the expence. This county yields the finef flate, and abundance of excellent hams are cured here. The principal rivers are, the Eden, the Lone, and the Ken. It has alfo feveral fine lakes, the principal of which is Winander Mere, or Windermere water. In the Eoreft of Martindale, to the fouth of Ulls-water, the breed of red deer ttill exifts in a wild ftate.- Appleby is the county town.

WESTPHALIA, formerly a duchy of Germany, bounded to the ealt by the biflopric of laderborn, and the territories of Waldeck and Heffe; to the fouth by the counties of Witgentein and Naffau, and the duchy of Berg; to the north by the bihopric of Munfter and the county of Lippe. It is about 40 miles in length and 30 in breadth. The lower part of it is very fruitful, yielding plenty of corn and cattle, and fome falt fprings. The higher affords iron ore, calamine, lead, copper, fome filver and gold, fine woods, cattle, game, fifh, with a little corn. The rivers, that either pals through the duchy or along its borders, are the Kahr, the Lunne, the Bigge, the Dimel, and the Lippe. There are 28 towns in it, befides boroughs and cloifters. The provincial diets are held at Arenferg. In the year 1180, the emperor Fred. I. made a donation of this duchy to the arclibithopric of Cologne, which was confirmed by fucceeding emperors; and in 1638 , the laft duke of Arenberg ceded to it alfo the county of Arensberg.

Westrhalta, one of the circles of Germany, anciently the people inhabiting between the Wefer and the Rhine, were called Wefphalians; and hence that tract got the name of Wenphalia: but the circle of that name is of a larger extent, being furrounded by the circle of Burgundy, or the Auttrian Netheriands, the United Provinces, and the North fea, with the circles of the Upper and Lower Rhine, and comprifing a great many different ftates.

The fummoning princes and direntors of the circle of Weitphalia, were the bifhops of Munfter, alternately with the electors of Brandenburg and Palatine, as dukes of Cleve and Juliers. The archives belonging to it were before the war (1797) kept at Duffeldorp. Its quota of men and money is fomewhat more than the ainth part of the whole fur granted by the empire. With refpect to religion, it is partly Proteftant and partly Catholic ; but the Proteftants predominate, and are, at lealt the greater part of them, Calvinifts. The air of this country is not reckoned very wholefome, and towards the north is extremely cold in winter. The foil in general is marlhy and barren; yet there is forme good corn and pafture land ; but the fruit is chietly ufed to feed hogs; and hence it is that their bacon and hams are fo much valued and admired.

Weftphalia now forms one of the kingdoms eftablifhed by Bonaparte.

WESTRINGIA, a genus of plants, formed from runila frumicofa, which was difcovered by Dr Solander in New Holland. Dr Smith defaibes it as approaching nearer to rofemary, and places it after teterium in the clais didynamia.

WET-coucri, Coming-heop, a term ufed by the maltfiers fo: one of the principal articles of malt-making. See Brewing, \(\mathrm{N}^{\circ} 4\).

father's

W: iftin.
II
Wharten.

Wharton. father's exprefs order at liome. He very early marricd a young lady, the daughter of Major-General Holnes, which difappointed his father's views of difpofing of him in fuch a marriage as would have been a confiderable addiion to the fortune and grandeur of his illultrious fanily; yet that amiable lady deferved infinitely more felicity than foce met with by this alliance. This precipitate marriage is thought to have haftened the death of his father; afier which the duke, being free from paternal relltainis, plunged into thofe excelfs which rendered him, as Pope expreffes it,
"A tyrant to the wife his heart approv'd;
"A rebel to the very king he lov'd."
In the beginning of the year 1716, he began lis travels; and as he was defigned to be inftructed in the fricte: Whing principles, Genera was thought a proper place for his refidence, He firt paffed through Holland, and vifited feveral couris of Germany; and being anived at Geneva, conceived fuch a difgut againt his governor, that he left him, and fet out poit for Lyons, where he wrote a letter to the chevalier de St George, who then refided at Avignon, and prefented him a very fine flout horfe; which the chevalier no fooner received than he fent a man of quality to him, who took him privately to his court, where he was entertained with the greatell marks of etheem, and had the titie of duke of Northumberland conferred upon him. He, however, remained there but one day, and then returned poft to Lyons, whence he fet out for Paris. He likewife paid a vifit to the confort of James II. who then refided at St Germains, 10 whom he alfo paid his coutt. During his fay at Paris, his winuing addrefs and abilities gained him the effeem and admiration of all the Britifh fubjects of rank of both parsies.

About the latter end of December 1716 , he arrived in England, whence he \{oon afier fet out for Ireland, where, though under age, he was allowed the honour to take his feat in the houfe of peers, and immediately diftinguihed limilelf, notwithllanding his former conduct, as a violent partizan for the miniltry; in confequence of which zeal the king created him a duke. He no fooner came of age than he was introduced to the houle of lords in England with the fame blaze of reputation. In a little time he oppofed the court, and appeared one of the moft vigorous in defence of the bifhop of Rochefter; and foon atier printed his thoughts twice a-week, in a paper called the True Briton, feveral thoufands of which were circulated.

The duke's boundlefs profution had by this time fo burdened his eflate, that by a decrce of Chancery it was velled in the hards of truttees for the payment of his debts, allowing him a provifion of 12001 . per amum for his fubfiftence. This being infufficient to fupport his title with fuitable dignity, he went abroad and flone to great advantage, with relpect to his perfonal character, at the imperial court. From thence he made a tour to Spain : the Englifh minifter was alarmed at his arrival, fearing that his grace was received in the charafter of an ambaftadar: upon which the duke received a fummons under the privy. feal to return home; hut inftend of obeying it, he endeavoused to intlame the Spanifh court againf that of Grcat Britain, for exercifing an act of power, as he calls it, within the jurifdiction of his Catholic majelly. He then acted openly in the fervice
of the Pretender, and was received at his court with the Whatovi. greateft marks of favour.

While his grace was thus employec', his neglected duchers died in England on the \(14 t h\) of \(A_{\text {pril }} 1726\), without iflue. Soon after the duke fell violently in love with M. Obernc, one of the maids of honour to the queen of Spain, the daughter of an Irill colonel, whoic forture chiefly, confifted in her perfonal accompliflments. All his friends, and particularly the queen of Spain, oppofed the match; but he falling into a lingering fever, occafioned by his difappointment, the queen gave her confent, and they were foon after married. He then fpent fome time at Rome, where he accepted of a blue garter, aflumed the title of duke of Northumberland, and for a while enjoyed the confidence of the exiled prince. But not always keeping within the bounds of Italian gravity, it became nectfary for him to remove from hence; when, going by fea to Barcelona, he wrote a letter to the king of Spain acquainting him that he would affift at the fiege of Gibraltar as a volunteer. Soon after he wrote to the chevalier de St George, exprefling a defire to vifit his court ; but the cheralier advifed him to draw near to England.

The duke feemed refolved to follow his advice; and fetting out with lis duchefs, arrived in Paris in May \({ }^{1728}\), whence he foon after proceeded to Rouen, where he took up liis yefidence; and was fo far from making any concefion to the government of England, that he did not give himfelf the leaft trouble about his eflate, or any other concern there; though, on his arrival at Rouen, he had only about 6ool. in his pofiefficn, and a bill of indictment was preferred againf him in England for high-treafon. Soon after the clevalier fent him 20001 . which he fquandered away in a courfe of extravagance; when, to fave the charges of travclling by land, he went from Orleans to Nantz by water, and flaid there till lie got a remittance from Paris, which was fquandered almoft as foon as received. At Nant\% he was joined by his ragged fervants, and from hence took hlipping with them for Bilboa, when the queen of Spain took the duchefs to attend her perion. About the beginning of the year 1731, the duke, who commanded a regiment, was at Leerida, but declined fo faft that he could not move without affiftance; yet when frce from pain did not lofe his gaiety. He, however, received benefit from fome mineral waters in Catalonia; but foon after relapled at a fmall village, where he was utterly deflitute of all the neceffiries of life, till fome charitable fathers of a Bernardine convent ren:oved him to their houfe, and gave him all the relief in their power. Under their hofpitable roof he languified a week, and then died, without one friend or acquaintance to clofe his eyes; and his funcral was performed in the fame manner in which the fathers inter thofe of their own fraternity.

Thus died Pirilip duke of Wharton, "who, like Buckingham and Rochefter (fays Mr Walpole), comforted all the grave and dull, by throwing away the brighteft profufion of parts on witty fooleries, debaucheries, and fcrapes, which mix graces with a great character, but never can compofe one.
" With attachment to no party, though with talents to govern any party, this lively man changed the free air of Weftminter for the gloom of the Efcurial, the profpect of King George's garter for the Pretender's;

Wharton, and with indifierence to all religion, the frolic lord who \(\xrightarrow{\text { Whasth }}\) \(-\) had written the ballad on the archbinhop of Canterbury, died in the habit of a capuchin. It is dilficult to give an account of the works of a man whofe library was a nevern, and women of pleafure his mufes. A thoufand fallies of his imagination may have been lofl. There are only two volumes in 8 vo , called his Life and Writings. Illcfe contain nothing of the latter, but it numbers of the True Briton, and his fipeech in defence of the billop of liochetter. His other works are the ballads above mentioned; the Drimking Match at Eden-hall, in imitation of the Chery Chace, printed in a mifcellany called Whrurtoniana; and a parody of a fong fung at the opera-houfe by Mrs Tofts. His lordthip alfo began a play on the flory of the queen of Scots."
wheat. See Trimeur, Botany Index; and for the culcure of wheat, fee Agbicuiturf. Index.

The three principal kinds of bad wheat are, the blighed, the finutty, and the zeorm-aten. Blighted wheat is that of whicl the flalk is a little twifted and rickety, the blade being of a bluifingreen and curled up, the grain alfo is green and tubercled: finutty wheat appears as if great part of the ear had been burnt, fome frall parts only being fiee, and, in particular, the fem that rifes in the centre of the ear, round which the grain is ranged : worm-eaten or rotten wheat is corrupted without lofing much of its natural form, or external apyearance; the liufk is filled with a greafy black powder, that is infulferably fetid. It appeared, from the experiments of M. Tillet, that there was a kind of infectious quality in all thofe kinds of wheat: fo that if found wheat was fprinkled with the flour of fmutty or rotten wheat, the crop produced would be rotten or fmulty. It appeared alfo, that among the grain which was produced from ground manured with the ffraw of difempered wheat, thicre was a much greater proportion of dintempered wheat than in that produced from ground manured with the ftraw of good wheat: the great fecret then was to deftoy the principle of this contagion in the wheat that was put into the ground; and M. Tillet found, as the refult of a great number of experiments, that if the grain, before it is fowed, be well moiftened with a folution of fea-falt, or nitre, in common water, none of the enfuing crop will be finutty, or otherwife defective, either in kind or quality; not only fuppofing the grain that is fowed to be found, and the foil to be good, but even fuppofing the grain to be firewed with the flour of finutty wheat, and the ground manured with bad itraw.

The following receipt for preventirg funtty wheat was publified in 1769 by order of the Socicty for the Encouragement of Arts: they received it from Mr John Reynolds of Adifham in Kent.

A tub is to be procured that has a hole at bottcm, in which a faft and tap-hofe is to be fixed over a whifp of itraw, to prevent any fmall pieces of time paffing (as in the trewing way) ; this done, we put 70 gallons of water, then a corn buftel heap-full of fonc-lime, unflaked, nirring it well till the whole is diffolved or mixed, letting it fand about 30 hours, and then run it of into another tub as clear as we can (as prachifed in beer): this generally produces a hogftead of good ftrong limewater; then add three pecl:s of falt, 42 pounds, which, with a lithe firring, will foon बififolve; thus we have
prize Diy
jcrtation b ony of Bour distux.
a proper pickle for the purpofe of brining and liming our feel-wheat without any manner of obflacle, which is mone than can be faid in doing it the common way, and greatly facilitates the drilling.

Ifercin we fteep the wheat in a broad-bottomed bafket of about 24 inclies diameter, and 20 inches deep (for large fowing, made on purpofe), sumning in the grain gradually in fraall quantities from so to 12 gallons up to is gallons, firring the fame. What floats, we frim off with a fraines, and is not to be fown: then draw up the bafket to drain over the pickle, for a few minutes; all which may be performed within half on hour, fufficiently pickled; and fo proceed as before. -This done, the wheat will be fit for lowing in 24 hours, if required; but if defigred for drilling, two hours pickled will be found belt ; and if prepared four or five days beforehand, in either cafe it makes no diference at all; but fhould the feed be clanmy, and flick to the notches in the drill-box, inore lime inuft be added to the lime-water; here the mafter muft ufe his difcretion, as the cafe requires; for fome lime has much more drying or allringent qualities in it than others. If fea-water can be obtained conveniently, much lefs falt will fuftice, but fone will be found neceffary even then, otherwife the lisht grains will not Hoat, a thing of more corifequence than is generally imagined, and it ought to be flkimmed off and thrown afide for poultry, \&c.

WHEEL, in Mechanics, a fimp!e machine, confifting of a round piece of wood, metal, or other matter, which revolves on its anis. See Mechanics.

Wheel-Carriajes. Sce Mechanics for an account of the general principles.

No kind of wheel-carriages are of more importance to a commercial and manufacturing country than ftage coaches; and perhaps in no kingdom of Europe has the fyltem of travelling in public vehicles been carnied to greater perfection, as to comfort and fpeed, than in Britain. The danger, however, of travelling by thele coaches makes confiderable deduction from their accommodation otherwife: it is but too well known that this mode of travelling is liable to frequent and ferious accidents. Every attempt therefore that promifes to be ufcful in diminiflhing fuch danger fhould have all poffible publicity. With this view we are much gratified in having an opportunity of laying before our readers the following account of an invention to render fage coaches more fecure from danger, obligingly tranfinitted to us by the inventor, the reverend William Milton of Heckfield, Hants. For this invention that gentleman has obtained a patent.

The darger of fage coaches arifes fometines from overturning, and fometimes from breaking down. The overturn is, in general, occafioned either by teking two fide-whecls into too deep a hole or ditch, or over too high a bank; or, fecondly, by ruming down more quickly than the carriage is calculated to do, from the top to the fides of a rounded road; or, laitly, by turning a hiarp comer with too great velocity. In the two firft cafes the danger arlfes from the centre of gravity of the total coach and load being placed too high; and in the laft intance, of turning the fharp corner, from the fame centre (hut which we muft now confider as the centre of the vis inertice) bcing alfo placed too high. The danger in the two firft cales grows often out of the very circumftances of the road, and meets every one's

4 T 2
comprehenfion :

Whear, Wbectcarriages.

\section*{W H E 00 W H E}
compreherinon: the laf, which is lefs obvious, is generally owing to the mere will of the driver ; and the better the road, the more is he tempted, without any intention, to go on to produce it: it requires therefore to be more generally underftood than it is. It may be thus explained:-A. carriage is going along a fraight level road at the rate of nine miles an hour: then, though you imagine the horfes or pulling porrer to be in an inMant withdrawn, yet will the carriage continue its motion for ten, fifteen, or more yards, and at firt with the fame velopity, and in the fame fraight line, in confe. guence of the acouired morion. Suppofing, now, the coach with its four horfes going the nine miles an hour along a fine level road, but which has a flarp and fudden corner to turn; - the coachman knows it, and wifhes to keep his velocity; the horfes are aware of bothand by the animal dexterity with which they are gifted, contrive to make the turn without remitting any thing of their fpsed. Not fo the coach which follows them; that has a tendency to perfevere in its fraight line; and the centre of its effort to do to is the centre of its vis inertice, the very centre of its gravity. If this centre be low, the turn of the corner may be made with no other inconvenience than a fhort awkward flide of the hind wheels, onuard in the original dircefion; whereas, if it be high, there will be no flide, but the coach will be overturned, and overturncd nearly at that point where its broadfide is at reetangles to the fraight line of road it has been thus forced to quit : for at that point the bafe againft fuch an overturn will be the moft difadvantageous, and the check to the onward motion the greateft. The remedy offered againft all thele caufes of the overturn, (whether by a sitch, bank, rounded road, or foarp corn( \(\cdot\) ), is to bring down this centre, by placing as much of the luggage as polible in a luggage-box, below the body of ille carriage; the body not being higher than ulual.

From the overturn, we pals to the confaderation of the breaking-dozun; this we muft reckon on happening as often in thefe patent fage coaches as in others. Wheels will come of or fail, or axles will break, in future, as they have done heretofore; but againt the difaffrous and fatal confequences of fuch accidents the remedy offered may be thus defcribed.-On each fide of the luggege-box, with their periphery below its floor, and each as near as may be requilite to its refpective active wheel, there is placed a fmall frong idle wheel, ready in cafe of breaking down, on either fide, to catch the falling carriage, and inflantly to continue its previous velocity, till the coachman can pull up his horfes, thereby preventing that fudden flop io rapid motion, which at prefent conitantly attends the breaking-down; and which has fu frequently proved fatal to the coachman and outfide paliengers. In cafe a fore-wheel comes off, each end of the fore-carriage has its idle wheel. By this provifion we thall be, to all effect of fafety, continually travelling with two carriages under us.' The bottom of this Inggage box is meant to be ahout fourteen inclies from the ground; and the idle whecls feven, fox, or five; but if at a ftill lefs diftance, little inconves:ience would refult; for when cither of them takes over an cuftacle in the road, it intlantly, and during the need, difcharges its refpective achive ovhed from the ground, and works in its flead. If thefe two principles of fafety were applied to the defeription of the feveral lagc-coach accidcnts we mect with, there is no doubt
but a general conviction would arife, that the fafety by thefe modes is (in velicles of all kiiids), perlaps as grata as can confif with rapid loco-motion; and !lat, fooner or latter, legillative authority, in fonse thape or other, may judge it neceffary to interpofe, for the pur. pole of controlling a prejudice agnintt the form effer. tial of this modic of fafety. 'I he trial and proot which thefe principles lave been brouglat to, have not only. been by public exhibition, and with prepration; but in all che fundennefs, alfo, of actual heaviy work: and the refult in both cafes has been fo exactly the lame, as to. give continual a flurance of the full effect of the remedy, as often as the cafualties of the road fall bring it into action.

The aim in the arrangement of this coach of fafety. has been to bring down the load, and confequently the center of gravity, as low as poffible: this is thought to make the coach look heavy; and this word, by the ready operation of a prejudice, has been transferred to its going; and one Specific reafon added withal, that, becaufe the lond is low, the draught mufl be heavy. 'This point, however, has, in the prefence of 10 or I2 competent perfons, been brought to the mof decifive proof; and it comes out, that it is as indifferent to draught, as it is material to danger or fafety, whether a ton be placed on the roof of a coach, or a ton on the floor of the patent luggage-box, about 15 or 16 inches from the ground.

It has been anked, "W"lat would this coach do in fnow?" The queftion has been thas anfwered by the refult of actual work; for the patent coach, after being detained on the road with feveral other coaches, by a fudden fall of fnow, when at latt they flarted together, came in fix or feven hours before any of them. They were bound in prudence, to go cautioufly along the ground, whofe unevennefs was invifible; while the patent coach dabed along it with all the confidence and fafety of a poft-chaife. See Plate DLXXVII.

Wheel-Animal. See Animalcule, \({ }^{0}\) I 6-23.
ITheel, Perfian. See Agriculture.
W'heel, Polter's See Porcelain.
Whesel is allo the name of a kind of punifhment to which great criminals are put in divers countries. In fome, aflaflins, parricides, and robbers on the highway, are faid to be condemned to the wheel, when they are to have their bones firft broken with an iron bar on a fcafold, and then to be cxpored, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itfelf.-Of this cruel puinflment, it is not certain who was the inventor: it was firt ufed in Germany, and was, indeed, but rarcly practifed anywhere elfe, till the time of Francis I. of France; who, by au edict of the year 1534 , appointed it to be inflicted on robbers on the highway.

WHEELER, Sir GEORGE, a learned traveller and divine, was the fon of Colonel Wheeler of Charing in Kent, and was born in 1650 at Breda, where his parents as royalifts were then in exile. He travelled through various parts of Greece and the Ean, in company with Dr lames Spon of Lyons; and taking orders on his return, was inftalled a prebend of Durham, made vicar of Pafingfoke; and afterward rector of Houghom le Spring. He publifhed an account of his Travels in 3682 in folio; and in 1689 , his Obfervations on Anciont Edifices of Churches yet remaining in the Eaft.

iecliings compared with Éurebius: alfo the Proteflant Monafery, or Chriftian Oeconomics. He died in 1724.
- WHEELINGS, in the military art, are diffrent motions made both by horfe and foot, wither to the sight and left, or to the right and left about.
General Rules for Wheritina-The circle is divided into four equal points: thence, whecling to the right or left, is only a quarter of the circle; whecling to the right or left about, is onc halt of the circle.
When you wheel to the right, you are to clofe to the right, fo near as to touch your right hand man, but nithout preffing lim ; and to lock to the left, in ordes to bring the rank about even.
When you wheel to the left, you are to clofe to the left, and look to the right as above directed. This rule will ferve for all the wheeling by ranks; as when a battalion is marcling by fubdivifions with their ranks open, then each rank whecls diftinctly by itfelf, when it comes to the ground on which the ranks before it wheeled, but not before.
In wheeling, the men are to take particular care neither to open nor clofe their ranks, and to carry their arms well.
In wheeling, the motion of each man is quicker or flower, according to the ditance he is from the right or the left : thus, when you wheel to the right, each man moves quicker than his right-hand man ; and wheeling to the left, each man moves quicker than his leit-hand man! ; the circle that every man wheels being larger, according to the diftance he is from the hand he whieels to; as may be feen by defrribing feveral circles within one another, at two feet diflance from each, which is nearly the fpace every man is fuppofed to take up.
WHELK, a fecies of fhell-fill. See Buccisun, Coxchology Indes.
WHELP, the young of a dog, fox, lion, or any wild beart.
Wheips, in a flip, the feaman's term for thofe brackets which are fet up on the caplan tlofe under the bars ; they give the fweep to it, and are fo contrived that the cable winding about them may not furge fo much as it might otherwife do if the body of the cap. flan were quite round and fmooth.
WHETSTONE, a flone fo called, becaufe it ferves for the whetting of edge tools upon. See Minfralogy Index.
WHEY, the ferum or watery part of milk.
WHIDAH, a kingdom of Africa, on the coaft of Guinea, and to the weft of the Gold Coant ; extending about 10 miles along the fea. It is a populous country, well furninied with large villages; and there are fo many fmall ones, that they are not above a mulfet-fhot from each other.-The lioufes are finall, round at the top, and encompanied with mud walls or hedges, together with a great number of all forts of beautiful and lofty trees, which afford the moft beautiful profpect in the world, infomuch that thofe that have been here reprefent it as a perfeet paradife. The fields are always green, and they cultivate beans, potatoes, and fruits; nor will the negroes here let a foot of ground remain uncultivated. They fow again the very next day after they have reaped. The inhabitants are greatly civilized, very refpectuil to each other, efpecially to their fuperiors, and very induftrious. The women brew the beer, drefs the vifuals, and fell all for!!s of commoditios

701 3. W H I
at the market. 'Yhofe that are rich employ their wives and flaves in tilling the land, and they carry on a confiderable trade with the product, as well as in flaves; for fome of them are able to deliver 1000 of the latter cvery month. The clief men have generally 42 or 50 wives, the principal captains 300 or 400 , and the king 4000 or 5000 . They are extremely jealous, and, on the lealt fufpicion, will fell them to the Europeans for naves. If any one happen to touch one of the King's wives accidentally, he is doomed to perpetual flavery. It is no wonder then that the women are not fond of being the king's wives; and fome of them will prefer a fpeedy death to fuch a mifcrable life. They have no diftinction of houra, days, weeks, mionths, or years. The rite of ciscumcifion is ufed here; but they are not able to tell why they ufe it, nor whence it is derived. They are fuch great gamefters, that they will flake all they have at play, not excepting their wives and children. They have a vaft number of idols; and they deily the moft contemptible animal that they fee that in a morning, and even flocks and fones. Their principal regard is for fnakes, very high trces, and the fea. An Englifh fator, juft arrived, found a fnake in the houfe belonging to the factory, and killed it without the leaf fruple; which fo incenfed the negrocs, that they were for revenging the death of the frake, not orly upon him that killed it, but upon the whole fatiory; but by means of prefents, and the interpofition of the pecple of the other factories, the affair was made up, and the tinake honourably interred. However, to prevent fuch accidents, they gave them warning not to do the like for the future. They have oxen, covs, goats, fleep, logs, turkeys, ducks, and hens; which laft are extremely pleutiful. There are many elephants, buffaloes, tigers, feveral kinds of deer, and a fort of hares. The fruits are cittons, lemons, oranges, bananas, tamarinds, \&c. and they have vait numbers of palm-trees, from which they obtain wine. Whidah was conquered by the king of Dahony. Their trade confift of flaves, elephants teeth, wax, and honey. The Englifh factory is 300 miles eaft of Cape Coaft Cafte, within land. Bows, arrows, beautiful aflaguays, and clubs, are the principal weapons of the nation.
whidaw-Btrd. See Emberiza, Ornithology Index.

WHIG, a perfon belonging to a political party in Britain, oppofite to the Tories. See Tories, and Britan.

Whimbrel. See Scolopax, Orxithology Inder.

Whin. See Ulfx, Botany Index.
tVhinchat. See Motacilla, Ornithology Index.

WHIP, or WhIP-Staff, in a hip, a piece of timber, in form of a ftrong ftaff, faftened into the helm, for the fleerfman, in fmall fhips, to hcid in his hand, in order to move the rudder, and direet the fhip.

WHIR LPOOL, an eddy, vortex, or gulf, where the water is continually turning round.

Thofe in rivers are very common, from various accidents, and are ufually very trivial, and of little confequence. In the fea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirpool among the Orcadcs, which. would prove very dangerous to frangers, tbough it is

Whidsb: Whiripord.

\section*{W H I [ 702]}

\section*{W II I}

Whirlpeol, of no confequence to the people who are ufed to it. Whirhwind.

This is not fixed to any particular place, but appears in
various parts of the limits of the fea among thefe illands. Wherever it appears, it is very furious; and boats, \&uc. would inevitably be drawn in and perith with it; but the people who navigate them are prepared for it, and always carry an empty veficl, a \(\log\) of wood, or large bundle of fraw, oi fome fuch thing, in the boat with them; as foon as they perctive the whirlpool, they tofs this within its vartex, leeping themfelves out : this fubfance, whatever it be, is immediately received into the centre, and carried under water; and as foon as this is done, the furface of the place where the whirpool was becomes fmooth, and they row over it with fafety; and in about an hour they fee the vortex begin again in fome other place, ufually at about a mile's diftance from the firlt.

WHIRLWIND, a wind which moves in a firal direction, as well as horizontally, which is exceedingly rapid and impetuous, but only of mort duration.

Dr Franklin's opinion of the origin of whirlwinds has been already given in the article WATER-Spout. If his theory be true, it will follow, that no hurricane ever can be fo violent as to remove an obftacle of the fize of oaly one cubic inch, provided that was fupported by a porver equivalent to 15 pounds; for this is the utnoit force of the atmofphere when rufhing into a perfect vacuum, which never could take place in the centre of a whirlwind or water-fpout. Indeed, notwithftanding the drcadful effects fometimes oblerved from hurricanes and whirlwinds, we falll eafily perceive, that the utmoft of their power always falls very far fhort of this. The diminution of the Jpecific gravity of the air by only onefourth in the middle of the column, would produce fuch an aftux of air from all quarters, that an obflacle prefrnting a furfice of one foot fquare, would require a force of 504 pounds to prevent it from being carried away; which the ftrongeft walls that can be built by human art could farce refitt. Nay, even the tenth part of this, or the diminution of the gravity of the atmofphere by one-fortieth part, would produce a preffure of upwards of \(s 0\) pounds on every fquare foot of furface, which, it is to be doubted, whether any of our commen houles could refilt.

Some philofophers afcribe the vacuum in the atmofplere, to which, according to Dr Franklin's theory, whirlwinds are owing, to a ftream of electric matter rufhing with violence into the atmofyhere out of the earth. But they do not inform us how this matter comes to be accumulated in that part of the earth; what induces it in pals out of the earth; how it paffes invifibly through pure air ; or what ferves it for a conductor. It leems to be the falhion among certain philofophers to afcribe every phenomenon, with the cawfe of which we a e unacquainted, to electricity. But this is merely fubflituting a new namc, and ferves rather to retard than advance our knowledge of nature.

Some kinds of whirlwinds move with a llow motion, and are injurious only by their vortex; while others feen to do mifchief as well by their progetine as their whirling motion. Of this kind are thofe called typhons; which, by their frequently following the courle of rivers, feem thus alfo to difcover their cleatrical origin. Of the deftructive cifects of thefe, we have an inflance ir what happened in Charleflown in South Carolina, on
the ift of Juac \(576 \pm\). It was fuft obferved about noon, Whirlwis. on land, upwards of 50 roileswent by fouth of Charlestown, and deftroyed feveral houfes, \&c. as it paffed along, in many places making wide avenues through the woods; from whence every tree and firub was torn up, and great branches of trees were driven about in the column as it pafled along. It cireeted its counte to Amley river, down which it came with furprifing velccity ; in its appearance refembling a column of fmoke or vapour, whole motion was very irregular and turnultuous. Its momentum was fo great, that Afhley river was floughed to the botom, and the channel laid bare. As it came down this river, it made a conflant noile like thonder; its diameter being computed about 300 fathoms. It was met at White Point by another of the fame kind which came down Cooper's river, but with inferior Arength; however, on their meeting together, the agitation of the air was mucls greater, while the clouds, which were driving in all directions to the place, feemed to be precipitated, and whirled round with incredibie velocity. It then fell upon the ftipping in the road ; cntirely deftroying fome, and daraging others; being farce three minutes in its paffage, though the diftance was near two leagues. In that thort time it did damage to the amount of \(20,000 \mathrm{l}\).; and had not its direction been altered by that guft which came down Cooper's river, it muft have totally deftroyed Charleftown, as no obftacle whatever feemed capable of refiting its fury.

WH1SKY, a term fignifying water, and applied in Scotland and in Ireland to a difilled liquor drawn from barley.

WHISPERING-places. See Acclstics, No 24.
WHIS'I, a well known gane at cards, which requires great attention and fience; hence the name.

This game is played by four perfons, who cut for partners; the two higheft and the two lowet are tegether, and the partners fit oppofite to each other: the perfon who cuts the lowet card is to deal frot, giving one at a time to each perfon, till he comes to the lati card, which is turned up for the trump, and remains on the table till each perfon has played a card. The perfon on the left hand fide of the dealer plays firt, and whoever wins the trick is to play again, thus going on till the cards are played out. The ace, king, queen, and knave of trumps, are called honours; in cafe any theree of theie honours have been played between, or by either of the two partners, they recken for two points towards the game; and if the fuur honours have been played between, or by cither of the two partners, they rection for four points towards the ganc, the game confilling of ten foints. The honours are reckuned after the tricks; 211 above fix tricks reckoning allo towards the game.

Cicneral Ruies for playing the Game of II'HIST.1. He who is to play firft hould lead from the Arongest fuit. If he has a fequence of king, queen, and knave, or queen, knave and ten, he may fafely lead the highent of the fequence; bat if he has five or fix in number, he muft begin with the loweft. He mult always begin with the higheft trump, by which he forces out the fuperior trumps, and can come in again, to make his fiong fuit.
2. He fhould never be afraid to play trumps when he has five in his hand, tven of ibe fmallet, although lae may not have any good cards of any other fuit.
3. With ace and king of any two fuits, and only two or three fmall trunps, the aces and kings fhould be played out, in order to make as many tricks as poffible; and having but two or three fmall trumps, he floould never force his partner to trump, if he finds he cannot follow fuit; but endedvour to chrow the lead into his parther's hand.
4. He fhould in general return his partner's lead, unLefs he bas fome capital cards of his owro.
5. As this game is played with the hurcl, that is, to fave haif the flake, five poims mull be made befure the game is out: he fhould not venture to play trumps when the is four of the game, unlefs he is very firong, having at leaft an honour and three trumps, or ace, king, and two fmall oncs.
6. When the game is fcored nine, at which ftage the honaurs reckon for nothing, he thould be ftill more cautions how he plays trumps, even if he is ftrong in hand, and give his partner an opportunity of trumping the adverfaries fuits, in cafe he is deficient in them.
7. If his adverfaries are fix or feven love of the game, he fhould play a forward or bold game, that he may have a chance, at the rifk of a trick or two, to come up with them. If he has but three trumps and other good cards, he may play arumps, efpecially if he has a fequence, or queen, knave, and a fmall one.
8. He mould always rifk a trick or two when the game is much in his favour; becaufe a new deal is of greater confequence to the adverfary than one or two points are to him.
9. When the player finds there is a likelihood of either faving the game or his lurch, he flould rifk the odd trick; but if the game is five all, and he can make two tricks in his own hand, he fhould make them, in order to fecure the difference of two points, which make the game near two to one in his favour.
10. A good player thould begin with a fmall trump, when he has ace, ling, and four fmall ones; for this reafon, if his partner, has a better trump than the laft player, which is an equal wager but he has, he has a chance of fetching out all the trumps, by having three rounds of them.
31. The odds are always in his favour that his partner holds an honour; confequently if he has king, queen, and four fmall ones, he flould begin with a fmall one.
12. When queen, knave, and four fmall trumps are dealt him, he fhould play a fmall one firf, the odds heing in his favour that his partner holds an honour; if he has knave, ten, and four fmall trumps, he Bould alfo begin with a frall one, for the fame reafon.
13. If he has knave, ten, eight, and three fmall trumps, the knave mould be played firt, by which means the nine may be prevented from winning a trick, the odds being in his favour that three honours are played in two rounds.
14. If an honour is turned up again! him on his left hand, and he has ten, nine, and eight, with two or three fmall trumps; when he is to play, he flould play through the honours with the ten, which will force the dealer to
play his honour to a difadvantage, if the dealer does not choofe to leave it to the option of his adverfary whether he will pals it or not ; but if he has fix trumps of a lower denomination, and not ten, nine, and eight, and no honour turned up againf him, he fhould begin with a fmall one.
15. In general, when he has two capital cards in trunips, and two or three finall ones, he fhould begiss with a Ginall one, for the reafon affigned in \(\mathrm{N}^{\circ} 12\).
16. When he has ace, king, knave, and two fmall trumps, or even one fimall trump, by firf playing the king, and putting the lead inio his partner's hand, who will phay a trump; judging him to have ace and knave, from his beginning with the king: in this cafe the knave fhould be fineficd (A), nothing being againl him but the queen.
17. If he has knave, ten, eight, and (wo (mall trumps, by playing the knave freft, it is odds but in two rounds of trunts the nine falls, or be may finctle the eight when his partner returns trumps.
18. With five trumps of a lower denomination, he thould begin with the frualleft, unlefs he has a fequence of ten, nine, and eight; then he flould begin with the ten.
19. When he has king, queen, ten, and one fmall trump, he muft begin with the king, and wait for his partner's return of the trumps, in order to finefle the ten, by which means he may win the knave.
20. In order to prevent the ten from winning, whe:1 he has queen, knare, nine, and one fmall trump, he mult begin with the queen. And in care he has knave, ten, eight, and one fmall trump, he fhould begin with the knave, that the nine may not win.
in. If he has ten, nine, cight, and one frall trump, he fhould begin with the ten; thereby he frengthens his partner's hand, leaving it at his option to take it oi: not.
22. He thould begin with a fmall one, when he has the ten and three fmall trumps.
23. If he has a good frit, and ace, king, and four fmall trumps, he mult play three rounds of trumps, in order to fecure his Atrong fuit from being trumped.
24. When he has king, queen, ten, and three fmall trumps, he fhould begin with the king, becaufe he has a chance of the knave's coming down in the fecond sound; and to fecure his frong fuit, he fhould not wait to fineffe the ten. If he fhould have queen, knave, and three fral! trumps, and fonse good fuit to make, he muft begin with a fmall one.
25. If he has knave, ten, eight, and two fmall trumps, with a frong fuit, he thould begin with the knave, in order to make the nine fall in the fecond round; but if he las knave, ten, and three fmall trumps, with a good fuit, he fheuld play a fimali one firft.
26. With ten, nine, eight, and one fmall trump, provided he has a good fuit, he fhould begin with the ten; by which means he may get the crumps out, and have a chance of making bis ftrong fuit.
The following obfervations will enable a player to know that his partner has no more of a fuit which either
(A) Finefle, is to play a fmall card which may win, keeping the fuperior. card or cards to lay over the right. hand adverfary.

Whis．of them has played．Suppofe lie leads from queen，ten， nine，and two fmall cards of any fuit，the fecond hand puts on the knave，his partner plays the eight；in this cafe，he having queen，ten，and nine，it is a demonftra－ tion，if his partner plays well，that he can have no more of that fuit．By that difcovery，he may play his game accordingly，either by forcing his partner to trump that fuit，if he is frong in trumps，or by playing ano－ ther fuit．If he has king，queen，and ten of a fuit， and he leads his king，his partner plays the knave；this alfo demonftrates he has no more of that fuit．If he has king，queen，and many more of a fuit，and begins with the king，in fome cafes it is good play in a partner， when he has the ace and one fmall card in that fuit on－ ly，to win the king with the ace；for fuppofe the part－ ner to be very flrong in trumps，by taking the king with the ace，he gets the lead and trumps out，and hav－ ing cleared the board of trumps，his partner returns his lead；and the ace being out，there is room for him to make that whole fuit，which could not have been done if the partner had kept the ace．Suppole he has no other good card in his hand befides．that fuit，he lofes nothing by the ace＇s taking his king；and if it flonld fo happen that he has a good card to bring in that f⿴囗十 he gains all the tricks which he makes to that fuit by this method of play：as his partner has taken his king with the ace，and trumps out upon it，he has reafon to imagine that his partner has one of that fuit to return him；for which reafon he fhould not throw away any of that fuit，even to keep a king or queen guarded．

Method of playing when an honour is turned up on the right hand．－Suppole the knave is turned up on his right hand，and that he has king，queen，and ten；in order to win the knave，he muft begin with the king；by which means，his partner may fuppofe him to have queen and ten remaining，efpecially if he has a fecond lead，and he does not proceed to play the queen．

Suppofe the knave turned up as before，and he has ace，queen，and ten，by playing his queen，it anfwers the purpofe of the former yule．

W＇hen the queen is turned up on his right hand，and he has ace，king，and knave，by playing his king，it an－ fwers the fame purpofe of the former rule．

In cafe an honour is turned up on his left hand，fup－ pofing he fhould hold no honour，he fhould play tromps through the honour as foon as he gets the lead；but if he fhould hold an honour（except the ace），be muft be cautious how he plays trumps，becaufe，in cafe his part－ ner holds no honour，his adverfary will play his own game upon him．

Method of playing the fequences．－The highet in fe－ quences of trumps fhould be played，unlefs he bas ace， king，and queen；and then he fhould play the louef， which informs his partner of the ftate of his game．

When he has king，queen，and knave，and two fmall ones，which are not trumps，he fhould begin with the knave，whether he is ftrong in trumps or not，as he makes way for the whole fuit by getting the ace out．

If he is Arong in trumps，and has a fequence of queen， knave，ten，and two fmall cards of a fuit，he lhould play the higheft of his fequance；for if cither of the adverfa－ ries flould trump that fuit in the fecond round，being alfo frong in trumps，he will make the remainder of that fuit，by fctching out the trumps．When he has
knave，ten，and nine，and two fmall cards of a fuit，he whin． may play in the like manner．

If king，queen，and linave，and one fmall card of any fuit，is the cafe，whether frong in trumps or not，he fhould play the king；and when there are only four in number，the fame metiod of play thould be obferred by inferior fequences．
－When weak in trumps，he fhonld begin by the loweft of the fequence，provided he has five in number，becaule if his partner has the ace of that fuit he will make it． If he has the ace and four fmall cards of a fuit，and weak in trumps，leading from that fuit，he fhould play the ace．When ftrong in trumps，the game may be played otherwile．

How to make a fam，or win every trick．－Suppofe A and \(B\) partners againtt C and D ，and C to deal， A to have the king，knave，and nine，and feven of hearts； which are trump：，a quart－major in fpades，a tierce－major in diamonds，and the ace and king of clubs．Then fup－ pofe B to have rine fpades，two clubs，and two diamonds． Alfo fuppofe D to have ace，quecn，ten，and eight of trumps，with nine clubs，and \(C\) to have five trumps and eight diamonds．A leads a trump，which \(D\) wins，and \(D\) is to play a club，which his partner \(C\) is to trump；\(C\) lends a trump，which his partner \(D\) wins；\(D\) then will lead a club，which C will trump；and C will play a trump，which D will win；and D häving the beft trump will play it；after which D having feven clubs in his hand，makes them，fo that he flams \(A\) and \(B\) ．
How to play any hand of cards according to the nearef？ calculations of his partner＇s holding certain winning cards：
1．That he has not one certain winning card，is

2 to 1
2．That he has not two certain winning cards，is

17 to 2
But it is about 5 to 4 that he has one or both，or

32 to 25
3．That he has one card out of any three certain winning cards，is about．

5 to
4．That he has not three certain winning cards is about 31 to 1 ，or

681 to 22
5．That he has not two of them，is about 7 to 2，or

547 to 156
6．That he has not one of them，is about 7 to 6，or
\(37^{8}\) to 325
7．That he holds one or two of them，is in his favour about 13 to 6 ，or
\(4^{81}\) to 222
8．And about 5 to 2 that he holds 1,2 ， or all three of them．
The ufe of thefe calculations is for a whit－player to play his cards to the molt advantage．For inflance，

As the firf calculation is two to one that his partner does not hold one certain kimning card．－Suppofe then a fuit is led，of which the fecond player has the king and a fmall one only，he thould put on the king，be－ caufe the odds are in his favour，that the third player cannot win it．For the fame reafon，when he is fe－ cond player，and to lead，he flould play a king in pre－ ference to a queen，becaufe it is two to one the ace does not take it；but it is five to four the queen will be taken by either ace or king，which may be in the third． hand．

According

Whit, Whitton.

According to the fecond calculation, of its being five to four that his partner holds one certain wimning card out of any two: If he has two honours in any fuit, he can play to an advantage, knowing it is five to four in favour of his partner's having one of the two bonours; and by the fame rule, if he is fecond player, having a queen and one fmall card, by playing the queen he plays five to four againt himfelf.

It is obvious, from the third calculation, which proves it to be five to two that his partner has one card out of any three certain winning cards, that he who plays the knave fecond hand, having but the knave and one fmall card of the fame fuit, mult play five to two againt himfelf, and difcovers his game to a great diladvantage; for which reafon, he mould play the lowef of any fequence which he may hold in his liand, as the knave, if he has king, queen, and knave; the ten, if he has queen, knave, and ten, \&c. By fo doing, his partner has an opportunity of judging what card to play in that fuit, according to the odds for or againft him.

From the above calculation, if he has ace, king, and

Cambridge, Mr Whiton fettled in Londun; where, without fuffering his zeal to be intimidaied, he continued

Whifion, Whily: to write, and propaçate his Pimitive Chrittianity, with as much ardour as if he had been in the moll gourilhing , ir cumitances. In 1721, a fublcription wav aade for che fupport of his fatnily, which amounted to \(4 \% \mathrm{ol}\). For though he deew profits from reading affronuxical and philolophical lectures, and allo from his publications, which were vety numerous, yet theli of themfelves would have been very infufficient: nor, when joiaed with the benevolence and charity of thole who !oved and efeemed him lor his learning, integrity, and piety, did they prevent his being frerpenily in great diflrels. Ite continned long a member of the c! surch of England, and segularly frequented its fervice, theur, he dilapproved of many things in it: but at laft he went over to the Baptifs, and attended Dr Forter's meeting at Piancr's hall, Liroad. ftrect. Among other performances not fpecified above. he wrote Memoirs of his oun lite and writings, which contain fomc curious particulars.

He weas remarkable for lpeaking the plainell truths on every occafion, and to perfons of every degre: During the year 1725 , that he, with Dr Clarke, Dr Besholcy, and others, had the honour to allend gueen Carmate on a certain day of every week, to talk of the ping.els of fcience, her majefly one cyening took uccehon to pay him a jult complinneil on his truth and integricy, requelting that he would, with his ufual plamets, point out to her any fault that he might have oblerico in her conduct. At firt he begged to be exculed, adding, that few perfons could bear to have their faults planhey told to them, and leaft of all royal perfonages, whe, fiom their elevation, are neceflarily furmunded by thatterers, to whofe lips truth is a ftranger. Her majefty, replied, that he was to confider her not as a gucen, tut as a philofopher; and that phitofophy is of very little ute, if it cannot enable its profeflors to bear without cffence truths neceffary to their own improvement. Upois tiis he told her, that the greate? fault which lie had oblerved in her conduct, was her indecont behaviuur in the houfe of God, which, he affured her, had made very unfavourable impreffions on the minds of many perfons, who coming to town from diftant parts of the country, had gonc to the chapel to obtain a fight of her majefy, the king, and the royal family. The queen made no reply; but in about fix weeks afterwards renewed her requedl, that Mr Whifon would point out the moit glaring improprieties in her conduct. To this he anfwered, that he had laid down a maxim, from which he could not deviate, never to point out to any perfon more than one fault at a time, and never to give a fecond reproof till he had obferved fome good confequence to have arien from the firt (A). Much to the qqueen's honour, fhe was pleafed with this plain-dealing, and contured to think favourably of Mr W'histon. This honell, but whimfical and credulous man, died in 1762, at the advanced age of 95.

WHITBY, Dr Daniel, a very learned Englih divine, was born at 1638 , and bred at Oxford ; where, in \(166 \frac{1}{4}\), he was elected perpetual fellow of his college. He afterwards becane chaplain to Dr Seth Ward, bi4 U
fhop
(A) Bimop Berkelcy was prefent at thefe corverfations, and from his fon we received the account we have given of them. They are likewife mentioned, but not fiated fo accurately, by Bifhop Newton in his own Life.

Whitby Whit:field
thop of Salifury; who collated him in 1668 to the prebend of Yatefbury in that church, and foon after to that of Hufborn and Burbach. In 1672 lie was admitted chanter of the faid church, on the death of Mr Iuhn South, and then, or foon after, rector of St EJmund's church in Salifoury. He was made a prebendary of Taunton liegis in \(\mathbf{6 g} 6\), and died in 1726 . He was ever ftrangely ignorant of woridly affairs, even to a degree that is farcely to be conceived. His uritings are numercus, and well known; particularly his Commentary on the New Tefament.

Whitey, a fea-port town in the north riding of Yorknire, feated on the river ERE, rear the place where it falis into the fea. The houfes are neat, ftrong, and convenient; the number of inhabitants aboui goce. Suip-building is their principal employment. W. Long. 0. 24. N. Lat. 54. 30.

WHITTE, one of the colours of natural bodies.
ITHITE of the Eye. denotes the firf tunic or coat of the eye, calied albuginea. See Anatomy, No 142.

White of Erg. See Alduaies and Egg.
IWHITE Friars, a name common to feveral orders of monks, from being ciothed in a white habii.

White Ses, is a bay of the Frozen occan, fo called in the north part of Mufcovy, lying between Rulian La;land and Samoieda; at the bottom of which fands the city of Archargel. This was the chief port the Rufinans had before their conqueft of Livonia.

IVHTE Colour, white lead for painting. See ChesMISTRY, No 1856.

WIITE Iron, or Tin-plate, iron-plates covered over with tin; for the method of making which, fee Latten, Chimistry, No 1956.

In 168 i lin-plates were manufactured in E.ngland by one Andrew Yarranton, who bad been fent to Bohemia to learn the method of making them. But the manufacture was foon afterward, difcontinued. It was revived in 1740 , and has now arrived at as great, if not greater, perfection in this country than in any other.

White Lead. See Cilenistry, No 1856.
'White-Throat. Sce Motacilla, Ornithology Index.

WHITEFIELD, George, the celebrated preacher among the people called Mcihodif/s, was born in the year 1714, at the Bell in the city of Gloncefter, which was then kept by his mother. At about 12 years of age he was put to a grammar-fchool; but his mother entering into a fecond marriage, which proved a difadvantageous one, he, when about 15 , put on a blue apron, and ferved her in the capacity of a drawer or waiter. After continuing about a year in this fervile employ. ment, fie turned over the bufinefs to his brother ; who marrying, and George not agreeing with his fifter inlaw, he left the inn. Some time after, meeting with an old fchool-fellow, then a fervitor in Pembroke college, Osford, he was induced to attempt getting into the fame collcge in a like capacity, and fuccceded. Here Mr Whitefield, who from his own account appears to have always had a ftrong tincture of enthufiafm in his confitution from his very childhood, diftinguilhed himfelf by the aufterity of his devalion, and acquired confiderable eminence in fome religious aflemblies in that city. At the age of 21 , the fame of his piety recommended him fo effectually to Dr Benfon, then bifhop of

Gloucefter, that he made him a voluntary offer of ordination. Immediately after this regular adorifion iato the minifty, Mr Winitefield applied himfelf to the molt extraordinary, the moft indefatigable, dutics of his cl:aracter, preaching daily in prifons, fields, and open frectc, wherever he thought there would be a likielihood of making profelytes. Hasing at length made himelf univertally hnown in England, he embarked for Ame: lica, where the tencts of Meihodifm began to fpread very faft under his friends the Wefleys; and firt decormined upon the inflitution of the orphar-houfe at Georgin, which he afterwards offected. After a long courfe of peregrination, his fortune incleafed as his tame ex. tended among his fullowers, and he crected two very extenfive buildings for public worhip, under the name of Tabernacles; one in Mottenlam-Cuurt Road, and the ather in Moorfields. Here, with the help of fome affiftans, he continued for feveral years, attended by very crowded congregations, and quiting the kingdom only occafionaily. Befides the two tabernacles alieady mentioned, Mr Whitcficld, by being chaplain to the countefs dowager of Huntingdon, was connected with two other religious mectings, one at Bath, and the other at Tunbridge, chiefly erecied under that lady's patron. age. By a lively, fertile, and penetrating genius, by the moft unwearied zeal, and by a forcible aind perfuafive dc. livery, he never failed of the defired effect upon his cever crowded and admiring audiences. In Amesica, however, which always engaged much of his attention, he was deftined to finih his courfe; and lee died at Newberry, about 40 miles from Bofton in New England, in 1770 .

WHITEHAVEN, a fea-purt town of Cumberland, with a mathet on Tucfday, and one fair on Augufl ift for merchandife and toys. It is feated on a creek of the Irih fea, on the north end of a great hill, walled by the tide of flood on the woft fide, where there is a large rock or quamy of hard white fone, which gives name to the place, and which, with the help of a Arong foncwall, fecures the harbour, into which fmall barks may enter. It is lately much improved in its buildings, and noted for its trade in pit-coal and falt, there being near it a valuable coal-mine, which runs a confiderable way under the fea. They have a cuftom-houfe here; and they carry on a good trade to Ireland, Scotland, Chefter, Briftol, and other parts. It is io miles fouthweft of Cockermouth, and 305 north-wefl of London. W. Long. 3. 34. N. Lat. 54. \(3^{6}\).

WHIIENESS, the quality which denominates or conftitutes a body white.

Whites, or Fluor Albus. See Medicine, No \(25 c\).

WHITING. See Gadus, Icuthyology Index.
WHI'llow, or W'hitloe. See Surgery Index.
WHITSUN.Farturnes, otherwife called Smokefarthings of Quadrames Pentecofiales, a compofition for offerings which were anciently made in Whitfur-week by every man in England, who occupied a houle with a chimney, to the cathedral church of the diocefe in which be lived.

WHITSUNDAY, a folemn feftival of the Chrilian church, obferved on the fiftieth day after Eafter, in memory of the defcent of the Holy Ghoft upon the apofles in the vifible appearance of fiery cloven tongucs, and of thufe minaculous powers which were then conferred upon them.
this being one of the ftated times for baptifim in the ancient church, thofe who were baptifed put on white garments, as types of that fpiritual purity they received in baptifm. As the defcent of the Holy Gholt upon the apollles happened upen the day which the Jews called Pentecuf, this Ceftival retained the name of Pentccoll amones the Claritians.

Whitsuepiar jle, one st the New Ilebrides, which lies about four miles to the fouth, runs i:s the fame dirce. tion, and is of the fame length, having more floping expofures than Aurora: it appears to be better inhabited, and to contain more plantations.

WhORTLEBERRY. See Vaccinum, Rotiny Index.

WHY'II, Dr hosfrrt, an cminent plyfician, born at Eanburgh on the 6th September \(1 \frac{1}{1} 4\), was the fon of liobert Whytt, Efq. of Bennochy, advocate. This gentleman died lix months before the birth of our author, who had allo the misfortune to be deprived of his mother before he had attained the feventh year of his age. After recciving the firt rudiments of fehonl-education, he was lont to the univerfity of St Andrew's; and after the ufual courle of inmuction there, in claffical, philofophical, and mathematical learning, he came to E limburgh, whore be entered upon the ftudy of medicine, under thofe eminent medical teachers, Monro, Rutherford, Sinclair, Plummer, Alfon, and Innes. After learning what was to be acquired at this univelfity, in the profecution of his ftudies he vifited foreign countries; and after attending the mof eminent teachers at London, Paris, and Leyder, he had the degree of Dottor of Phylac conferred upon him by the univerfity of Rheims in 1736 , being then in the 22d year of his age.

Upon his return to his native country, he had the fame honour alfo conferred upon him by the univerfity of St Andrew's; where he had before obtaincd, with applaufe, the degree of Mafter of Arts.

Not long afterwards, in the year 1737, he was admitted a Licentiate of Medicine by the Royal College of Phylicians of Edinburgh; and the year following he was raifed to the rank of a Fellow of the College. From the time of his admiffion as a licentiate, he entered upon the prattice of phyfic at Edinburgh; and the reputation which he acquired for medical learning, pointed him out as a fit fuccefior for the firt vacent chair in the univerfity. Accordingly, when Dr Sinclair, whofe eminent medical abilities, and perfuafive powers of oratory, had contributed not a little to the rapid advancement of the medical fohool of Elinburgh, found that thofe confpicuous talents which he poffefed could no longer he exerted in the manner which they once had been, when he enjoyed bodily vigour unimpaired by age and powers of mind unclouded by difeafe, he re. figned his academical appointments in favour of \(\mathrm{Dr}_{r}\) Whytt.

This admiffion into the college took place on the 20th of June \(174^{6}\); and he began his firt courfe of the infitutions of medicine at the commencement of the next winter-fefion. 'The abilities which he difplayed from his academical chair, in no particular difappointed the expectations which had been formed of his lectures. The Latin tongue was the language of the univerfity of Edinburgh; and he both fpoke and wrote in Latin
with fingular propriety, elegance, and perfpicuity. At
Wajlt. that time the fyftem and lentiments of Dr Boerhaave, which, notwithlanding their eirors, muft challenge tlee admiration of lateft ages, were very gencrally received by the mof intclligent phy ficians in Britain. I) Whytt had no fuch idle ardour for novelties as to throw them entirely afide becaufe he could not follow them in every particular. 'The inftitutions of Dr Bocrhave, there. fore, furn:thed him with a text for his lectures; and he was no lefs fucceffful in explaining, illuitrating, und eftablilhing the featiments of the author, when he could frecly acopt them, than in refuting them by clear, connected, and decifive arguments, when he had occafion to differ from him. The opinions which he himfelf pro. poled, were delivered and enforced with luch acutenefs of invention, fuch difplay of facts and force of argument, as could rarely fail to gain univerfal affent from his numerous auditors; but free from that felf-fulficiency which is ever the offspring of ignorance and conccit, he delivered his conclufioas with becoming modelly and diffilence.

Frum the time that he firf entered upon an academ:cal appointment, till the year 1756 , his prelections were confined to the inflitutions of medicine alone. But at that period his learned colleague Dr Rutherford, who then filled the practical chair, who had already taurlit medicine at ldinburgh with univerfal applaule for more than thirty years, and who had been the firft to begin the inlitution of clinical lectures at the Royal Infirmary, found it nece?tary to retire from the fatiguing duries of an office to which the progrefs of age rendered lim unequal. On this crilis Dr Whytt, Dr Monro, fen, and Dr Cullen, each agreed to take a fhare in an appointment in which their united exertions promifed the higheft advantages to the univerfity. By this arrangement fludents, who had an opportunity of daily witnefling the practice of three fuch teachers, and of hearing the grounds of that practice explained, could not fail to derive the moft folid advantages.

In thefe two departments, the inftitutions of medicine in the univerfity, and the clinical lectues in the Royal Infirmary, Dr Whytt's academical labours were attended with the mof beneficial confequences both to the Itudents and to the univerfity. But not long after the period we have laft mentioned, his lectures on the former of thefe fubjects underswent a confiderable change. About this time the illuftrious Gaubius, who had fuc. ceeded to the chair of Boerhaave, fapoured the world with his Injitutiones Pathologic. This branch of medicine had indeed a place in the text which Dr Whylt formerly followed; but, without detracting from the character of Dr Roerhaave, it may jullly be faid, that the attention he had beftowed upon it was not equal to its importance. Dr Whytt was fenfible of the improved fate in which pathology now appeared in the writings of Boerhave's fucceffor; and he made no delay in availing himfelf of the advantages which were then arforded.

In the year i762, his pathological lectures were entirely new-modelled. Following the publication of Gaubius as a text, he delivered a comment, which was read by every intelligent fludent with the moft unfeipned fatisfaction. In the?e lectures he collected and co:denfed the fruits of accurate obfervation and long experience, Erricleed by all the opportunitics of information

Whigt: which be bad enjoyed, and by all the difcernment which he was capable of exerting, they were juftly confidered as his moft finifled production.

For a period of more than twenty ycars, fluring which he was juftly held in the higheft effeem as a leeturer at Edinburgh, it may readily be fuppofed that the extent of his practice correfponded to his reputation. In fact, he received both the firft enoluments, and the highert honours, which could here be obtained. With extenfive practice in Edinburgh, he had numerous confultations from other places. Fis opinion on medical fubjects was daily requelled by his molt eminent contemporaries in every part of Britain. Foreigners of the firt diftinction, and celebrated phyficians in the moft remote parts of the Britifh empire, courted an intercourfe with him by letter. Befides private teftimonies of efteem, many public marks of honour were conferred upon him both at home and abroad. In 1752, he was elected a fellow of the Royal Society of London; in rybr, he was appointed firf phyfician to the king in Scotland; and in 1764 . he was chofen prefident of the Royal College of Phyficians at Edinburgh.

But the fame which \(\mathrm{D}_{\mathrm{r}}\) Whytt acquired as a practitioner and teacher of medicine, were not a little increafed by the information which he communicated to the medical world in different publications. His celebrity as an author was fill more extenfive than his reputation as a profeffor.

His frft publication, An Eflay on the Vital and other Involuntary Motions of Animals, although it had been begun foon after he had finithed his academical courfe of medical education, did not come from the prels till 1751; a period of fifteen years from the tine that he had finifhed his academical courfe, and obtained a degree in medicine: but the delay of this publication was fully compenfated by the matter which it contained, and the improved form under which it appeared.

The next fubjea which employed the pen of Dr Whytt was one of a nature more immediately practical. His Effay on the Virtues of Lime-water and Soap in the Cure of the Stone, firft made its appearance in a feparate volume in 1752. Part of this fecond work had appeared feveral years before in the Edinburgh Med:cal Effays: but it was now prefented to the world as a diflinet publication with many improvements and additions.

His third work, intitled Phy fological Effays, was firt publihed in the year 1755. This treatife confifted of two parts; ift, An Inquiry into the Caufes which promote the Circulation of the Fluids in the very fmall Veffels of Animals; and 2dly, Obfervations on the Senfioility and Irritability of the Parts of Men and other Animals, occafioned by \(\mathrm{Dr}_{\mathrm{r}}\) Haller's treatife on that fubjeet. The former of thefe may be confidered as an extenfion and farther illuftration of the fentiments which he had already delivered in his Eflay on the Vital MoSions, while the latter was on a fubject of a controverfal :ature. In both he difplayed that acutenefs of genius :nd firength of judgenent which appeared in his former writings.

From the time at which his Phyfrological Effays were pablifieci, Several years were probably employed by our author in preparing for the prefs a larger and perhaps a wore important work than any yet mentioned, his Ob.
fervations on the Nature, Caufes, and Cure of thofe Diforders which are commonly called nervous, hypochiondries, and lyysteric. This elaborate and uleful work was publithed in the year 1764 .
the latt of Dr Whytt's writings is intitled, Dbfervations on the Droply in the Brain. This treatife did not appear till two years after his death; when all his other works were collected and publithed in one quarto volume, under the direction of his fon and of his intimate friend the late Sir John Pringle.

Belides theie five works, he wrote many other papers, which appeared in different periodical publications; particularly in the Philofophical Tranfactions, the Medical Eflays, the Medical Oblervations, and the Phyfical and Literary Effays.

At an early period of life, foon after he had fettled as a medical practilioner in Edinburgh, he entered into the married flate. His firlt wife was Mifs Robertion, fifter to General Robertion governor of New York. By her he had two children; both of whom died in early infancy , and their rather did not long furvive them. A few years after the death of his firft wife, he married as a Fecond wife Mifs Balfour, filter to James Balfour, Efq. of Pilrig. By her he had fourteen children; but in thefe alio he was in fome refpects unfortunate; for fix of them only furvived him, three fons and three daughters, and of the former two are fince dead. Although the feeling heart of Dr Whytt, amidn the diftreffes of his family, mull have often fuffered that uneafinefs and anxicty which in fuch eircumflances is the unavoidable confequence of parental affection and conjugal love; yet he enjoyed a large thare of matrimonial felicity. But his courfe of happinefs was terminated by the death of his wife, which happened in the year 1764 : and it is not improbable that this event had fome flare in haftening his own death; for in the beginning of the year 1765 his health was fo far impaired, that he became incapable of his former exertions. A tedious complication of chronical ailments, which chiefly appeared under the form of diabetes, was not to be refifted by all the medical fkill which Edinburgh could afford; and at length terminated in death, on the 1 th of April 1766 , in the 52 d year of his age.

WIBURGH, a coufiderable town of Denmark, in North Jutland, with a bifhop's fee, remarkable for being the feat of the chief court of juftice in the province. The hall where the council affembles has the archives of the country, and efcaped the terrible fire that happened in the year 1726, and which burned the cathedralchureh, that of the Black Friars, the town-houfe, and the bithop's palace; but they have all been rebuilt more magnificent than before. It is feated on the lake Weter, in a peninfula, 25 miles north-weft of Slefwick, and 110 north-by-weft of Copenhagen. E. Long. 9. 50. N. Lat. 56. 20.

WICK, a royal borough on the eaft coaft of the county of Caithnefs. It is fmall, and the fireets narrow, but a few of its buildings are an ornament to the place. The prefent harbour is very inconvenient, but it is propofed to erect a new one, which will be of great importance to the fafety of navigation along that coaft. The population of the whole parift in 1793 amounted to 5000.
WICLER fignifies made of fmall twige.
WIChET, a fmall door in the gate of a fortified

\(+\)

\footnotetext{

} place,

Wiunse place, \&c, on a hoie in a door through which to view what paffes without.

WICKLIFF, lohn, the firt divine in Europe who had refolution to attempt a reformation of religion, was born about the year 1324, in the parifh of Wyclifi, near Richmond, in Yorkfhire. He was educated at Osford, frit in Queen's and afterwards in Merton college, of which he was a probationer-fellow. Having acquired the reputation of a man of great lcarning and abilitics, in 1361 he was chofen mafter of Baliol-hall, and in 3.35 conflituted warden of Canterbury college, by the founder Archbifhop Simon de Iflip; but in 1367, he was ejected by the regulars, together with three lecular fellows. He thought their proceedings arbitrary, and therefore appealed to the pope ; but inftead of obtaining redrefs, the cjectment was confirmed in \(\mathbf{1 3 7 0}^{3}\). This difappointment probably contributed fomewhat towards his enmity to the fee of home, or rather to confirm that cnmity; for he had long before written againgt the pope's exactions and corruptions of religion. However, his credit in the univerfity continued; for having taken the degrec of doctor in divinity, he read public lectures with great applaufe; in which he frequently expofed the impofitions of the Mendicant friars. About this time he publifhed a defence of his fovereign Edward 1 II. againft the pope, who had infifled on the homage to which his predeceffor King John had agreed. This defence was the caufe of Wickliff's introduction at court, and of his being fent one of the ambaffadors in 1374 to Bruges, where they met the pope's nuncios, in order to fettle feveral ecclefiaftical matters relative to the pope's authority. In the mean time Wickliff was prefented by the king to the rectory of Lutterworth in L.eicefterthire, and in 1375 he obtained a prebend in the church of Weftbury in Gloucefterihire. Wickliff continued hitherto, without moleftation, to oppofe the papal authority; but in 1377 a bull was fent over to the archbifhop of Canterbury, and to Courtney bifhop of London, ordering them to fecure this arch-heretic, and lay him in irons; at the fanc time the pope wrote to the king, requefting him to favour the biflops in the profeculion; he allo fent a bull to Oxford, commanding the univerfity to give him up. Before thefe bulls reached EngIand Edward III. was dead ; and Wickliff, protected by John duke of Lancafter, uncle to Richard II. favoured by the queen-mother, and fupported by the citizens of London, eluded the perfecution of Pope Gregory IX. who died in 1378 . In the following year this intrepid reformer prefented to parliament a fevere paper againgt the tyranny of Rome, wrote againt the papal fupremacy and infallibility, and publifhed a book On the Truth of the Scriptures, intended to prepare the way for an Englith tranflation of them, in which he had made confiderable progrefs. In 1381 he publifhed Sixteen Conclufions; in the firft of which he ventured to expofe the grand article of tranfubflantiation. Thefe conclufions being condemned by the chancellor of Oxford, Wick liff appealed to the king and parliament ; but being deferted by his unfteady patron the duke of Lancafter, he was obliged to make a confeffion at Oxford; and by an order from the king was expelled the univerfity. He now retired to his living of Lutterworth, where he finithed his tranflation of the bible. This verfior, of which there are feveral manufcript copies in the libraries of the univerfities, Britifh Mufeum, \& \(\varepsilon\). is a very literal tranlation
from the Latin vulgate. In \(13^{8} 3\) he was fuddenly Wirklif, fruck with the pally; a repetition of which put an end to his life in December 1384 . He was buried in his own church, where his bones were fuffered to reft in peacc till the year 1428 , when, by an order from the pope, they were taken up and burnt.-Befides a number of works that have been printed, he left a prodigious number of manufcripts; an accurate lift of which may be feen in Jiihop Jinner's Bib. Brit. Hil. Some of them are in the Bodleian Library, others in the Britifl Mufenm, \&c.

Wickliff was doubtlefs a very extraordinary man, confidering the times in which he lived. Ilis natural fagacity difcovered the abfurditics and impofitions of the church of Rome, and he had the honelly and refolution to promulgate his opinions, which a little more fupport would probably have enabled him to eftablift: they were evidently the foundation of the fublequent rcformation.

WICKL.OW, a county of Ireland, in the province of Leinfler ; bounded on the north by the county of Dublin; on the eall by the Irifl fea; on the fuuth by Wexford; and on the weft by Kiloare and Catherlough. It is 33 miles in length, 20 in breadth, and indifferently fruitful. It contains 54 parilhes, and formerly fent 10 members to the Irifh parliament.

Wicklow, the capital of a county of the fame name, in Ireland; feated on the fea-fide, with a narrow harbour, at the mouth of the river leitrim, over which ftands a rock, inftead of a caftle, furrounded by a ftrong wall, 24 miles fouth of Dublin. W. Long. 6. 7. N. Lat. 52. \(55^{\circ}\)

Widgeon. See Anas, Ornithology Inder.
WIDOW, a woman who has loft her hulband.
WIFE, a married woman, or one joined with, and under the protection of, an humand. See Husbaxil.

IsLe of WIGHT, an illand lying on the fouth coaft of Hampfhire, from which it is feparated by a narrow channel. It is about 21 miles in length and 13 in breadth. It is nearly divided into equal parts by the river Mede or Cowes, which rifing in the fouthern angle, enters at the northern, into the channel, oppofite the mouth of Southampton bay. The fouth-coalt is edged with very fteep cliffs of chalk and freeftone, hollowed into caverns in various parts. The weft fide is fenced with ridges of rocks, of which the moft remarkable are thofe called, from their ftarp extremities, the Needles. Between the ifland and the main are various fand-banks, efpecially off the eaftern patt, where is the fafe 1 oad of St Helen's. Acrofs the illand, from eafl to weft, runs a ridge of hills, forming a tract of fine downs, with a chalky or marly foil, which feed a great number of finc-llecced theep. Rabbits are alfo iery plentiful here. To the north of this ridge the land is chielly pafture : to the fouth of it is a rich arable country, producing great crops of corn. The variety of profpects which this ifland affords, its mild air, and the neat manner in which the fields are laid out, render it a very delightful fpot. It is devoted almof fulely to harbandry, and has no manufactory. It is ore of the principal refources of the London market for utimalted barley. Among its products are to be reckoned a pure white pipe-clay, and a fine white cryfalline fand ; of the latter of which great quantities are exported for the ufe of the glafs work in various parts. Its principal town is
the borough of Newport; it likervife contains the two finall boroughs of Newton and Yarmouth.

WIGTON, a royal borough, and capital of that ditrict of Galloway to which it gives name. It is of conficerable antiquity, and few of its houfes have been lately erected. It is fuppofed to have been a place of fome confequence in the ninth century, and that it was made a royal borough in the reign of Robert Bruce. It is governed by a provoft, two bailies, and I2 counfellors; is extremely healthy, and furnithes many inflances of longevity. In 1755, the population amounted to 1032, and the whole parifh in 1793 was 1350.

WIGTONSHIRE, fometimes denominated Upper or Wef Galloway, is about 30 miles long, and 12 broad. It is bounded on the fouth-eaft by the bay of Wigton, by which it is Separated from Kirkcudbright ; on the fouth and weft by the ocean; on the north by Ayrhire; and on the eaft by Kirkndbright. The coall is tolerably fertile, but improvements in agriculture are ftill in their infancy. The interior and northern parts are hilly and barren, fit only for fheep and biack cattle. It contains three royal boroughs, viz. Wigton, Stranraer, and Whithorn, with a number of feats belonging to noblemen and gentlemen. It is divided into 17 parithes; and, according to a cenfus taken fince the pafting of the population act in 1801, the population amounted to 22,918 , being an increafe of 6452 fince the return to Dr Webfter in 1755 . 'The valued rent is \(67,6,46\). Scots, while the real rent is computed at 53,8901. Aterling.

The following is the population according to the parifhes at two different periods * :

WhiD-Fire. See WTld-Fire.
WII.DFRNESS, in Gardening, a kind of grove of large trees, in a fpacious garden, in which the walks are commonly mate cither to interfect cach other in angles, or have the appearance of meanders and labyrinihs.

Wilderweffes (fays Mr Miller) fhould always be p:oportioned to the extent of the gardens in which they are made; for it is very tidiculous to fee a large wildernefs planted with iall trees in a finall foot of ground; and, on the other hand, nothing can be more abfurd than to fee little paliry fquares, of quarters of wildernefs-work, in a magnificent large garden. As to the fituation of wildernelies, they fhould never be placed too near the habitation, nor to as to oblruct any diftant profpect of the country, there being nothing fo agreeable as an unconfned profpect: but whete, from the fituation of the place, the light is confned within the limits of the garden, nothing can fo agreeably terminate the profpect as a beautiful tcene of the various kinds of trees judicioully planted; and if it is fo contrived that the termination is planted circularly, with the concave towards the fight, it will have a much better effect than if it end in Itraight lines or angles. The plants Thould always be adapted to the fizc of the plantation; for it is vory abfurd for tall trees to be planted in the fmall fquares of a little garden; and in large defigns fmall flrubs will have a mean appearance. It Chould alfo be oblerved never to plant evergreens among \(n\) deciduous trees; but always to place the evergreens in a wildernefs in a feparate part by themfelves, and that chiefly in fight.

As to the walks, thofe that have the appearance of meanders, where the eye cannot difcover more than twenty or thirty yards in length, are generally preferable to all others, and thefe fhould now and then lead into an open circular piece of grafs; in the centre of which may be placed either an obelilk, ftatue, or fountain; and if in the middle of the wildernefs there be contrived a large opening, in the centre of which may be erected a dome or banqueting houfe, furrounded with a green plot of grafs, it will be a confiderable addition to the beauty of the whole. From the fides of the walks and openings, the trees hould rile gradually one above another to the middle of the quarters; where fhould always be planted the largeft growing trees, fo that the beads of all the trees may appear to view, while their flems will be hid from the fight. Thus, in thofe parts which are planted with deciduous trees, rofes, honeyfuckles, fpirea frutex, and other kinds of low flowering furubs, may be planted next the walks and openings; and at their feet, near the fides of the walks, may be planted primrofes, violets, daffodils, \&c. rot in a ftaight line, but fo as to appear accidertal, as in a natural wood. Behind the firf row of lhrubs nould be planted fyringas, althea frusex, mezcreons, and other tlowering hurubs of a middle growth; and thefe may be backed with many other forts of trees rifing gradually to the middle of the quarters.

The part planted with evergreens may be difpofed in the following manner, viz. in the firl line next the great walks may be placed the laurunlinus, boxes, fpurge laurel, juniper, favin, and other dwarf evergreens. Behind there may be placed laurels, hollies, arbutufes, and other evergreens of a larger growth. Next to thefe may be planted alaternufes, phyllireas, ycws, cyprefles, Virginian cedars, and other trees of the fame growth; behind thefe may be planted Nor"ay and filver firs, the trtue pine, and other foets of the fir growth; and in the middle fhould be planted Scotch pincs, pinafter, and other forts of the larger growing

evergreens; which will alford a mon delighiful profpeet if the different thades of the grecus are curiounly intermixed.

But befile the grand walks and openings (whi h Ahould always be laid with turf, and kept well mowed), there fhonld lie fome fmaller ferpentine walks through the middle of the quarters, where porfons may retire for pievacy; and by the fides of thefe privite walks may alfo be fattcred fome wood-Howers and plants; which, if artfully planted, will have a very good cifect.

In the general defign thele wildernefies, there flowld not be a ftudicd and tliff correfposdency betwec:a the feveral parts; for the grater divelfity there is in the dillibution of them, the more pleafure they will af. forct.

WILKIE, WHLIIAN, D. D. authot of a heroic poem called the Epigoniad, was born in the parih of Dalmeny in Welt Lothian in Scotland, in October 1721. His father was a fmall farmer, and was not very fortunate in his worldly affairs. He gave his fon, however, a liberal education, the early part of which he received at the parilh fchool of Dalmeny, and at the age of \({ }_{3} 3\) he was fent to the univerfity of Edinburgh, where he was foon diftinguthed as a young man of genius. Among his fellow-fludents were Dr liubertion the hiftorian, Mr Home the poet, and fome other eminent literary characters. He became acquainted allo, in the courfe of his education, with David Hume and Dr Adam Fergu[on.

Before he completed his fludies at the univerfity, his father died, leaving him only the flock and mexpired leale of his furm, with the care of three fifters, one of whom being afterwards married to an experienced farmer, Wikie availed himelelf of his practical knowlelge. He formed a fyllem of farming which fully anfwesed his own expectations, and fecured to him the approbation of all his neirrhbours. After becoming a preacher in the church of Scotland, he ftill contiued his former mode of living, cultivating his farm, reading the claffics, and occafonally preaching for the minifers in the neighbourhood. In 1753, he was prefen:ed to the church of Ratho by the earl of Lauderdale, who was fenfible of his worth, and admired his genius. The duties of his new office he difcharged with fidelity, and was celebrated for his impreflive mode of preaching, while he did not negleet the amufements of hufonadry, and the ftudy of the belles lettres. He publihed his Epigoniad in the year 1757, the refult of fourteen years fludy, and a fecond edition of it was called for in 1759, in which year he was chofen profellur of natural philofophy in the univerfity of St Andrews. His whole fortune, when he removed to this place, did not exceed 200l. which he laid out in the purchafe of a few acres of land in the vicinity of the city. He lived in the univerfity in the fame fudious and retired manner as he liad done at Ratho. In the year 1768 he publifhed a volume of fables of no great celebrity, prior to which the univerfity conferred on him the degrec of D. D. He died, after a lingering illnefs, on the \(10 \%\) of OAnber 1772.

The manners of Dr Wilkie were in many refpects very fingular, and in fome quite difgulting. For the purpofe of promoting perfpiration, and thus remuving an aguih complaint, with which he had been Ceized during his refidence at Ratho, he generally flept in winter.
under no fewer than \(2 f\) blankets. His averfion to clean lin"w is altogether unaccountable. It is faid lath when he liept from home, lee not only fipulated for the pro- per 'luantity of biankets, but requefted to be indulged with theets which lad been proviounly ufed by tume other perfon. It is farcely necelfary to add, that his diefs was llowenly in the extreme. It is fumculatat remarkable, that Dr Wilkie never could read aloud the fmoutheni verle in fuch a manner as to preferve cither the meafure or the fenfe, althnugh his own compotitions in verfe are greatly dillinguiblad by their inoothacfs and elegrance.

It is faid that Dr Wilkic, from liaving fludied Momor with great attention, was led to project an epic poem on the model of that anciest poct. The fubject of it is drawn from the fourth bouk of the lliad, where Sthenclus gives \(\Lambda\) gamemnon a fhort account of the facking of Thebes; and as that city was taken ly the fons of thofe who had fillen tefure it, cur author gave to his poem the tille of Hpigoniad, from the Greek word ETryovor, fignifying defechdants. 'This title, it is fuppofed, is not very appropriate, and is not aliogether fice from quaintnefs. The fubject of the poem liats not been lelected with much judgement; for the learned reader will prefer futying the manners and actions of ancient hetoes in the fublime defcriptions of Homet and Virgil, and others will be little interefted in feenes ard characters fo diffetent from thofe with which they ate familiar, and fo far removed from their own times, Accordingly, the Epigoniad, with all its merit as an epic puem (and it is not dellitute of many of the effential requifites of that fpecies of poetical compofition), is now little known.

WILKINS, Dr Joits, a moft ingenious and learned Englifh bifhop, was the fon of a goldfmith of Oxford, and was born in 1614. He adhered to the parliament during the civil wars, by whom he was made warden of Wadham college in 1648: he married afierwards the filter of Oliver Cromwell, and procured a difpenfation to retain his wardenthip notwithflanding. Richard Cromwell made him maiter of Crinity college, Cambridge, from which he was ejected on the Reftoration. He then became preacher to Gray's-lim, rector of St Lanrence Jewty, London, dean of Rippon, and in 1688 was promoted to the bifthapric of Chefter. He died in 1672. Bihop Wilkins thought it prudent to fubmit to the powers in being; he therefore fubfribed to the folemn league and covenant while it was enforced, and was equally ready to fwear allegiance to King Charles when he was reltored: this, with his moderate fpirit toward diffenters, rendered him not very agreeable to churchmen. His mathematical and philofophical works, which contain many ingenious and curious pieces, confilering the time when they were written, have been collected in one vol. 8vo. He publithed alfo fome theological tracts. He was the firf prefident of the Royal Society.

WlLL, that faculty of the mind by which it embraces or rejects any thing offered to it. See Metaphysics.

Wile, or Lafl WILL, in Law, fignifies the declaration of a man's mind and intent relating to the difpofition of his lands, goods, or other eftate, or of what he would have done after his death. In the common law there is a ditinction made between a will and a tefta
ment: that is called a will where lands or tenements are given; and when the difpofition concerns soods and chattels alone, it is termed a teflament. See Testament.

WTLL-wilh-a-wifp, or Jach-wilh-a-lanthorn, two popular names for the meteor called isnis fatuus. See Ligit, \(\mathrm{N}^{\circ} 46\).

WILLIAM of Malmsbury, an hidorian of confiderable merit in the reign of King Stephen; but of whofe life few particulars are known. According to Bale and Pits, he was furnamed Somerfetur, fron the county in which he was born. From his own preface to his fecond book \(D e\) Regibus Anglormm, it apuears that he was addicted to learning from his youth; that he applied himfelf to the fludy of logic, plyfic, ethics, and particularly to hisory. He retired to the Benedidine convent at Malmbury, became a monk, and was made precentor and librarian ; a fituation which much favoured his intention of writing the hiftory of this kingdom. In this monaftery be fpent the remainder of his life, and died in the year 1142 . He is one of our molt ancient and moft faithful hiftorians. His capital work is that intitled De Regibus Anglorum, in five books; with an Appendix, which he fyyles Hiftorice Novella, in two more. It is a judicious collection of whatever he found on record relative to England, from the invafion of the Saxons to his own times.

WILLIAM of Newbury, fo called from a monatery in Yorkfhire, of which he was a member, wrote 2 hiflory which begins at the Conqueft and ends at the year 1197. His Latin flyle is preferred to that of Matthew Paris; and he is intitled to particular praife, for his honeft regard to truth, in treating the fables of Jeffery of Monmouth with the contempt they deferve; as well as vor expreffing his approbation of Henry II.'s defign of reforming the clergy, by bringing them under the regulation of the fecular power.

WILLLAM of Wykeham, bifhop of Winchefter, was born in the village of Wykeham, in the county of Southampton, in 1324. He was educated at Winchef. ter and Oxford; and having continued near fix years in the univerfity, his patron Nicholas Wedal, governor of the province of Southampton, took him into his family, and appointed him his counfellor and fecretary. He could not have made choice of a fitter perfon for that employment, no man in that age writing or fpeaking more politely than Wykeham. For this realon Edington, bifhop of Wincliefter, lord high-treafurer of the kingdom, appointed him his fecretary three years after, and allo recommended him to King Edward III, who took him into his fervice. Being fikilled in geometry and architecीure, he was appointed furveyor of the royal buildings, and alfo chief juftice in eyre: he fuperintended the building of Windior-cafte. He was afterward chief fecretary of Atate, a keeper of the privy feal ; and in 1367 fucceeded Edington in the fee of Winchefter, A little after he was appointed lord high-chancellor and prefident of the privy-council. That he might well difcharge the feveral functions of his employments, hoth ecclefiaftical and civil, he endeavoured, on one hand, to regulate his own life according to the frifteft maxims, and to promote fuch parih-priefts only as were able to give due inftruetions to their pariohioners, and at the fame time led exemplary lives: on the other hand, he did all in his power to caule juftice to
be impartially adminiftered. In \(137^{\text {r }}\) he refigned ins chancellorhip, and fome time after the great feal. Edward returning to England, after having carricd on a very fuccefsful war in France, found his exchequer in great diforder. The duke of Lancatter, one of his fons, at the head of Ceveral lords, having brought complaints againh the clergy, who then enjoyed the chief places in the kingdorn, the hing removed them from their employments. But the laymen, who were raifed to them, behaved fo ill, that the ting was forced to reftore the ecclefialtics. The duke of Lancatter fhowed ftrong animofity to the clergy, and fet every engine at work to ruin Wykeham. He impeached him of extortion, and of difguifing things, and abliged him to appear at the King's-bench. He got fuch judges appointed as condemned him ; and 'not fatisfied with depriving him of all the temporalities of his bithopric, he advifed Edward to banifh him: buit this prince rejected the propofal, and afterward reftored to Wykeham all that he had been divefted of. Richard II. was but eleven years old when Edward died: fo that the duke of Lancafter had an eafy opportunity of reviving the accufations againft the biftop of Winchefter: neverthelefs Wykeham cleared himfelf. Then he founded two noble colleges, the one in Oxford, the other in Winchefter. Whilf he was exerting his utmoft endeavours to improve thefe two fine foundations, he was recalled to court, and in a manaer forced to accept of the office of lord high-chancellor in 1389 . Having excellently difcharged the duties of that employment for three ycars, he obtained leave to refign it, forefeeing the difturbances that were going to break out. Being returned to his church, he finimed his college, and built there fo magnificent a cathedral, that it almof equals that of St Paul's in London. He laid out feveral fums in things advantageous to the public and to the poor; notwithfanding which, in 1397 he was in great danger ; for he and fome others were impeached of high-treafon in open parliament: however, he was again fully cleared. From that time till his death he kept quiet in his diocefe, and there employed himfelf in all the duties of a good prelate. He died in 1404 , in the 81 it year of his age.

Wilfiam, the name of feveral kings of England. See Efgland, \(N^{\circ} 87-92\), and Britain, \(N^{\circ} 302\).

Fort-WILlisim, a fortrefs in the Highlands of Scotland, erected in King William's reign, as was alfo a frall town adjoining, called Maryburgh, in honour of his queen. It is fituated in Invernefs-hire, on a narrow arm of the fea called Loch Eil, which by the completion of the Caledonian canal, will be united to the Weftern fea. Fort-William is of a triangular form, having tro baftions, and is capable of admilting a garrifon of 800 men ; but could not be defended againtt an attack, as it is commanded by feveral hills in the neighbourbood.

WILIILAM's Fort, is a factory of Afia belonging to the Eatt-India Company, feated on one of the branches of the river Ganges, in the kingdom of Bengal. The fort was firf built in the thape of an irtegular tetragon of brick and mortar ; and the town has nothing regular in it, becaufe every one built a houle as he liked bef, and for his own conveniency. The goremor's houfe is within the fort, and is the beft piece of architecture in thefe parts. Here there are allo conrenient lodgings for the factors and writers, with flore-houfes for the hout 50 yards fion the fort is the church, which was originally built by the merchants. The town of Catcutta is contiguous, containing 500,000 inhabitants. It is governed by a mayor and aldermen, as moft of the company's fa\&orios in the Eaf Indies now are. In 1757 it was furprifed by the nabob of Bengal, who took it, and put molt of thofe that had made refiltance into a place called the Black-Hole, where the greater number was fuffocated. This nabob was afterwards killed, and another fet up in his room, more friendly to the Engliflt; and the factory was re-cttablifhed. E. Long. 86. O. N. Lat. 22. 27. See Cal. cutta.

Sweet-Willitam. See Dianthus, Botany Index.
Williamsburg, a town of North America, in Virginia, and formerly capital of that ftate. It is fituated between two creeks; one falling into James and the other into York River. The diflance of each landing place is about a mile from the town, which, with the difadvantage of not being able to bring up large vefels, and the want of enterprife in the inhabitants, has occafioned its decay. Here is a college, defigned for the education of the Indians, but which, on account of their averfion to learning, never anfwered the purpofe. It is 60 miles eaft of Richmond. WV. Long. 76 . 30. N. Lat. 37. 10.

WILLIAMSTADT, a fea-port town of Holland. It is a handfome frong place, and the harbour is well frequented. It was built by William prince of Otange in 1585 ; and in 1732 belonged to the ftadtholder of Friefland. The river near which it is built is called Butterfliet or Holland Diep; and is one of the bulwarks of the Dutch on the fide of Brabant, where they always keep a garrifon. This place made a gallant defence in 1793 againft the French, who were obliged to raife the fiege. It is 15 miles north-oaft of Bergen-op-Zoom, and 12 fouth-weft of Dort. E. Long. 4. 30 . N. Lat. 51. 30.

Wíllis, Dr Thomas, a celebrated Englifh phyfician, was born at Great Bodwin, in Wilthire, in 1621, and fudied at Chrif-church college, Oxford. When that city was garrifoned for the king, he, among other fcholars, bore arms for his majefty, and devoted his leifure hours to the fludy of phyfic. The garrifon of Osford at length furrendering to the parliament, he applied himfelf to the practice of his profeffion; and foon rendered himfelf famous by his care and filll. He appropriated a room as an oratory for divine fervice according to the church of England, whither mof of the loyalifits in Oxford daily reforted. In 1660, he became Sedleian profefor of natural philofophy, and the fame year took the degree of doctor of phyfic. In 1664, he difcovered the famous medicinal fring at Alltropp, ncar Brackley. He was one of the firft members of the Royal Society, and foon made his name illuftrious by his excellent writings. In 1666, after the fire of London, he removed to Weflminfter; and his practice became greater than that of any of the phyficians bis contemporaries. Soon after his fettlement in London, his only fon Thomas falling into a confumption, be fent him to Monipelier in France for the recovery of his bealth; and it proved fuccefsful. His wife alfo labouring under the fame diforder, he offered to leave the sninn; but fhe, not fuffering him to neglea the means

Voc. XX. Part II.
of providing far his family, died in 1670. He died at his houfe in St Martin's in 1675, and was busied near her in Weftminfter-abley. 1)r Willis was extremely modelt and unambitious, and refufed the honour of knighthood. He was remarkably pious: As be rofe early in the morning, that he might be prefent at divine fervice, which lie comfantly frequented before he vifited his patients, he procured prayers to be read be yond the accuftomed times while he lived; and at his death fettled a ftipend of 201 . per annum to contirue them. He was a liberal benefactor to the poor wherecever be came, having from his carly praclice alloted part of his profits to charitable ufes. He was exact ard regular in all his hours: and though his table was the relort of moft of the gieat men of L,ondon, yet he was remarkable for his plainnefs, and his being a man of little difcourfe, complaifance, or fociety; but he was jufly admired for his deep infight into natural and experimental philofophy, anatomy, and chemillry; fur his fucceffful practice ; and for the elegance and purity of his Latin fyle. He wrote, r. A treatife in Englifh, intitled A plain and eafy Method for preferving thofe that are well from the Infction of the Piague, and for curing fuch as are infocted. 2. Several Latin woiks, which were collected and printed at Amflerdam, in 1682, in 2 vols 4 to.

WILLUGHBY, Francis, a celebrated natural hiforian, was the only lon of Sir Francis Willughby, knigh. He was fond of fludy from his childhood, and held idlenefs in abhorrence; he being fo great an economift with regard to his time, as not willingly to lofe or mifapply the leaft part of it, by which means he attained great fill in all branches of learning, and particula? ly in the mathematics. But to the hiflory of animals , which was in a great meafure neglected by his countrymen, he particularly applied himfelf; and for this purpofe carefully read over what had been writitn on that fubject by others. He then travelted feveral times over his native country; and afterwards into France, Spain, Italy, Germany, and the Low Countries, attended by his ingenious friend Mr John Ray. It is remarkable, that, notwithftanding the advantages of birth, fortune, and parts, he was as humble as any man of the meaneft fortune; was fober, temperate, and chafte; fcrupuloufly juft; fo true to his word and promife, that a man might venture his eftate and life upon it ; fo faithful and conftant to his friend, as never to defert him when fortune frouned upon him ; and remarkably pious, patient, and fubmiffive to the divine will. Tbis is the charakter given of him by Mr Ray, whofe veracity none will doubt. This ingenious and learned gentleman died in 1672 , at 37 years of aqe; having impaired his health by his application. He wrote, 1. Ornithologice libri tres, folio, which was afterwards tranflated into Engliih, with an Appendix, hy Mr Ray, in folio. 2. Hiforize Pifcium hibri quathor, folio. 3 . Letters of Francis Willughby, Efq. added to Philofophical Letters between the learned \(M_{r}\) Rey and feveral of his correfpondents, publifhed, in 8vo, by William Derham. 4. Several ingenious papers in the Plilofophical Tranfacions.

WILMOT. Johs, earl of Rochefter, a great wit in the reign of Charles II. the fon of Henry earl of Rochefter, was born in \(1 \sigma_{\ddagger} 8\). He was taught grammar and clafical learning at the free-fchoo! at Burford; 4 X
where

\section*{W I L [714] W I.I}

Hilmot. where he obtained a quick relifh of the beaties of the Latin tongue, and afterwards became well veifed in the authors of the Augultan age. In 1659 , he was admilted a nobleman of Wadham college, where he obtained the degree of mafter of arts. He afterwards tra. velled through France and Italy; and at his return was made one of the gentlemen of the bedchamber to the king, and comptroller of Woodftock Part. In 1665 he went to fea, and was in the Revenge, commanded by Sir Thomas Tiddiman, when an altack was made on the pert of Bergen in Norway: during the whole action he fhowed the greateft tefolution, and gained a high reputation for courage; which he fupported in a fecond expedition, but afterwards loft it in a private ad. venture with Lord Mulgrave.

Before the earl of Rochefter travelled, he had indulged in the moll diforderly and intemperate way of living; at his return, however, he feemed to have got the better of it entirely. But falling into the company of the courtiers, who continually practifed thefe exceffes, he became fo funk in debauchery, that he was for five years together fo given up to drinking, that during all that time he was never cool enough to be mafter of hinfelf. His violent love of pleafure, and his difpofition to evtravagant mirth, carried him to great cxcefles. The firf involved him in fenfuality, and the other led him into many adientures and ridiculous frolics. Once difguifing himfelf fo that he could not be known by his nearelt friends, he fet up in Tower-freet for an Italian mountebank, and there difper'ed his nottrums for fome weeks. He often difguifed himfelf as a porter, or as a beggar, fometimes to follow a mean amour; at other times, be would go about merely for diverfion, in odd fhapes; and afted his part fo naturally, that he eonld not be known even by his friends. In thort, by his confant indulgence in wine, women, and irregular frolics, he entirely wore out an excellent conftitution before he was 30 years of age. In October 1679 , when recovering from a violent difeafe, which ended in a confumption, he was vified by Dr Burnet, upen an intimation that fuch a vift would be agrecable to him. Dr Rurnet publifhed an account of his conferences with Lord Kocheher; in which it appears, that though he had lived the life of a libertine and atheift, yet he died the death of a penitent Chriftian. His death happened in 1680 ; fince which time his poems have been var:ous times printed, both feparately and together: but when once he obtained the character of a lewd and obfeene writer, every thing in that flrain was afcribed to him; and thus many pieces not of his writing have crept into the later editions of his works. The author of the Catalogue of Noyal and Noble Authors fays, he was s" a man whom the Mufes were fond to infire, and afianed to avow, and who practifed without the leaft referve that fecret which can make verfes more read for their defects than their merits. Lord Rochefter's Poems have much more obfcenity than wit, more wit than poetry, and more pcetry than politenels." His writings, befides thofe already mentioned, are, A Satire again Wankind; Nothing, a poem; Valentinian, a tragedy; Fifte-four Letters to Henry Saville, and others; Seven more to his Wife and Son : a Letter on his deathbed to Dr Bumet. He alfo left behind him feveral other papers, and a Hiftery of the Intrigues of the Court of

Charles II.; but his mother, a very devout lady, ordered Wilfon. all his papers to be burned.

WILSON, Florfnef, known in the republic of letters by the name of Florcntius Volufinus, was born at Elgin in the fhire of Murray in Scotland, and educated in the univerfity of Aberdeen. Travelling to England with an intention to improve his fortune, he had the felicity to be introduced to Cardinal Wolfey, who appointed him tutor to one of his nephews. In that capacity he went to Paris, and continued there till the cardinal's death. During his refidence in that city he becarne acquainted with the learned Cardinal Bellaj, archbifhop of Paris, who allowed him a penfion, and meant to have appointed him royal profefior of the Greek and Latin languages in the univerfity of Paris: but Bellai being difgraced, Wilfon's profpects faded with the fo:tunes of his patron, whom neverthelefs he attended on his journey to Rome. Wilfon was taken ill at Avignon, and the cardinal proceeded without him. After his recovery, he paid a vifit to the celebrated Cardinal Sabolet, the Mlecrenas of his time, who was alfo biftop of Carpentras, where he then refided. The cardinal was fo charmed with his erudition, that he appointed him profefior of the learned languages, with a fipend of roo piftoles per amum.

Dusing his refidence at Carpentras, he wrote his celebrated treatife Dc Animi Tranguilitate. Mackencie fays that he afterwards taught philofophy in Italy; and that, being at length definous of returning to Scotland, he began his journey homeward, was taken ill at Vieme in Dauphiny, and died there in the year 1547. He was generally efteemed an accomplifled linguin, an adminable philolopher, and an excelient Latin poet. He wrote, befide the above treatife, 1. Pocmata, London 1619, \(4^{\text {to. }}\) 2. Commentatio quadam theologica in aphorilmos diffecta, per Sebafl. Gryph. 3. Plilinophive Ario Mot. Synon/is, lib. iv.

Wilson, Thomas, lord bihop of Sodor and Man, was born in 1663, at Burton, in the county of Chefter. He received the rudiments of his education at the county town, and from thence was removed to the univerfity of Dublin. His allowance at the univerfity was 20l. ayear; a fum, fmall as it may now appear, which was in thofe days fufficient for a fober youth in fo cheap a country as Ireland.

His firt intention was to have applied to the fludy of phyfic ; but from this he was diverted by Archdeacon Hewetfon, by whofe advice he dedicated himfelf to the church. He continued at college till the year 1686 , when, on the 2gth of June, he was ordained deacon.

The exact time of Mr Wilfon's leaving Dublin is not knoun : but on account of the political and religious difputes of thofe days, it was fooner than he intended. On the roth of December, in the fame year, he was licenfed to the curacy of New Church in Winwick, of which Dr Sherlock, his maternal uncle, was rector. His fipend was no more than 3ol. a-year; but being an excellent economif, and having the advantage of living with lis uncle, this fmall income was not only fufficient to fupply his own wants, but it enabled him to fupply the wants of others; and for this purpofe lie fet apart one-tenth of his income. In 1692 be was appointed domeftic chaplain to William earl of Derby, and tutor to his fon James Lord Strange, with a falary of 301 a-year. He was foon afier elected matier of the nlingethoufe at Latham, which brought hin in 201. ayear more. Having now an income far beyond his expectations, or his wilhes, except as it increafed his abiIity to do good, he let apart one-fifth of his income for pious ules, and particularly for the poor. In flort, as his income increafed, he increafed the portion of it which was allotted to the purpofes of charity. At firft hic fet apart a tenth, then a fifth, aftel wards a third, and lafly, when he became a bihop, he dedicated the full half of his revenues to pious and charitable ufes.

He had not been long in the fervice of Lord Derby, before he was offered the valuable living of Buddefworth in Vioththire ; which he refufed to accept, as being inconfiftent with the refolves of his conlcience againlt non-rcfidence, Lord Derby choofing till to retain him as chaplain and tutor to his fon. In 1697 he was promoted, not without fome degree of compulfion oia the part of his patron, to the bilhopric of the Ifle of Man; a preferment which he held 58 years. In 1698 he married Mary, daughter of Thomas Patten, Efq. of Warriagton. By this lady, who furvived her marriage about fix years, he had four children; none of whom furvived hinn except the late Dr Wiiton, prebendary of Wetminfler.
"The annual receipts of the bihopric (fays the author of his memoirs) dill not exceed 3 col. in money. Some neceffaries in his houfe, as fices, fugar, wine, books, \&c. mult be paid for with money; difleffed or Shipwrecked mariners, and fome other poor objects, required to be relieved with mo:ley; but the poor of the jiland were fed and clothed, and the houfe in general fupplied from his demefnes, by exchange, without money. The poor, who could weave or fpin, found the bef market at Bifhop's-court, where they bartered the produce of their labour for corn. Taylors and froemakers were kept in the houfe confantly employed, to make into garments or thoes that cloth or leather which his corn had purchafed; and the aged and infirm were fupplied according to their feveral wants. Mr Moore of Douglas informed the editor, that he was once witnefs to a pleafing and fingular inflance of the Bifhop's attention to fome aged poor of the illand. As he was diftributing fpectacles to fome whofe eyefight failed them, Mr Micore expreffed his furprife, as he well knew, not one of them could read a letter. 'No matter (fiid the Bithop with a finile), they will find ufe enough for them; thefe fpectacles will help then to thread a needle, to mend their clothes, or, if need be, to kcep themelves free from vermin.?

So great was the bifhop's attachment to his flock, that no temptation could feduce him from their fervice. He more than once refufed the offer of an Englilh biAhopric. There is an anecdote of his lordhip and Cardinal Fleury, which does great credit to them both. The cardinal wanted much to fee him, and fent over on purpofe to inquire after his health, his age, and the date of his confecration, as they wete the two olden bithops, and he believed the pooreft, in Europe; at the fame time inviting hin to France. The biftop fent the cardinal an anfver, which gave him fo high an opinion of him; that the cardinal obtained an order that no French priyateer fhould rarage the ifle of Man.
\(\checkmark\) This good prelate lived till the year 1755, dying at
the advanced age of y.3. His works liave idelely been pulblithed in 2 vols 410.

WILTON, a market town in Withhic, three miles wefl of Salifbury. It was once fo confiderable as to give title to the county. It furmerly had I2 churches; and Odo, brother-in-law to William I. was billop of Wilton. Only one now remains. It iends members to parlianent, and is the place where the kniglts of the fhiee are chofen. It has a great inanufactory of carpets, which are brought to high perlection. Wilton in famous for Lord Pembroke's feat, fo well known through Jurope for its containing a grand afiemblage of the productions of the greateit and mofl ancient matters is painting and foulpture.-'Tivo fairs are held here annually.

WILTSFIIPE, a county of England, bounded on the well by Somerfethire, on the eait by Berkfhire and Hamphire, on the north by Gloucefterlhire, and on the fouth by Dorfethire and part of Hamphirc. 'The length amounts to 39 miles; its brcadtla to 30 ; and its circumference to \(\mathbf{1 4 0}\). It contains 29 hundreds, 2.3 market-towns, 304 parifhes, and about 135,107 fouls. Befides two members for the flire, and two for the city of Salifbury, each of the following towns fends two members to parliament, viz. Wilton, Downton, Hindon, Heytelbury, We?bury, Calne, Devizes, Chippanham, Malmflury, Cricklade, Great Bedwin, Judgerthall, Old Sarum, Wooton-Baffet, Marlborough.

The air of this county is very healthy, not only in the more low and level parts, but alfo on the liills. The loil of the vales is very rich, and produces corn and grafs in great plenty. The beattiful dowas in the fouth yicld the finelt palture for fheep, with which they are overfpread. The greatell difadvantage the county labours under is want of fuel, as there are no coal-pits, and but little wood. This couniy is noted for great quantities of very fine cheefe, and for its manufacture of broad cloth, to which it was invited by the great plenty and finenefs of its wool. Befides a number of lefter ftreams, it is watercd by the rivers Ific, K mnet, Upper and Lower Avon, Willy, Burne, anid Nadder, which arc well fored with filh.

WINCHELSEA, a town in Suffex, which has no market, but has one fair on May \(14^{\text {th }}\) for cattle and pedlars ware. It was an ancient place, at leaft the old town, which was fwallowed up by the cceain in 1250. It is norv dwindled to a mean place, though it retains its privileges, and Fends tixo members to parliament. It is feated on a rocky cliff, on an inlet of the fea; and had a haven, now choked up. It had 18 parih-churches, now reduced to one. The market-houfe is in the midh of the town, from whence run four paveif freets, at the end of which are four ways, which had formerly buildings on each fide for a confiderable diftance. It is two miles fouth-weft of Rye, and 7 I fouth-eaft of London. It is governed by a mayor and jurats, though it has but about 70 houfes. Three of the gates are fill fanding, but much decayed. E. Long. O. 44. N. Lat. 50. 58 .

Wincheisea, Anve Countefs of, a lady of excellent genius, elpecially in poetry, was maid of honour to the duchefs of York, fecond wife to King James II. and was afterwards married to Heneage, fecond fon of the earl of Winchelica. One of the molt co fiderable of the countefs of Winchelfea's poems was that on the

don in 1h13, containing a tragedy ncver acted, intitled Arjlomenss. 'The countefs died in 722 without iflue,
as her hufband did in 1726 .

WINCHESTER, the capital of the county of Hamplhire in England. It is a very ancient city, fuppofed to have been built feveral centuries before Chrift. The Romans called it Venta Belgaram, the Britons Caer Givent, and the Sasons Wittanceafitr; whence came the prefent name. It ftands upon the river Itchin, in a bottom furrounded with chalky hills; and is generally allowed to have been a confiderable place in the time of the Romans. Some of the firf conrerts to Chriftianity are fuppofed to have lived here. In the caftle, near the welt gate, many of the Saxon lings anciently kept their court. The cathedral was founded by Keneguife, a king of the Mercians; but there were many Chriltians, and places for their worthip here, long before that pesiod. It is a large pile, and has a vencrable look, but is not very elegant. Lefides the tombs, there are many curious pieces of workmanlhip in it; the chief of which are, I. The font, erected in the time of the Saxons. 2. Copper flatues of James I. and Charles I. 3. The biftiop's throne. 4. The ltalls of the dean and prebendaries. 5 . The afcent to the choir and altar. 6. The pavement, inlaid with marble of diverfe colours, in various figures. 7. The altar-piece, reckoned the nobleft in England. 8. The paintings in the windows, efpecially the great eall window. At the hofpital of the Holy Crofs, every traveller that knocks at the door may claim a manchet of white bread and a cup of beer; of which a great quantity is provided every day for that purpofe. This hofpital was intended for the maintenance of a malter and 30 penfioners, but only 14 are now maintained in it; and the malter enjoys a revenue of 8001 . a.year. This cily is aboust a mile and a balf in compats, and almolt furrounded with a wall of fint; has fix gates, large fuburbs, broad clean. Atreets; but the private houfes ate in general but ordinary, many of them being very old. The city is interfperfed with a great many gardens, which contribute to its beauty and healthinefs. The corporation confifts of a mayor, high-iteward, recorder, aldermen, two coroners, two bailiffs, 24 com-mon-council men, a town clerk, four contables, and four ferjeants at mace; and the city gives title of marquis to the duke of Bolton. A Roman highway leads irom bence to Alton; and went formerly, as it is thought, from thence to London. The charming downs is the neighbourhood contribute greatly to the health and plealure of the inhabitants. The river Itchin is navigable for barges from hence to Southampton. W. Long. 1. 21. N. Lat. 5 1. 5.

WINCKLEMAN, Abre John, was born at Stendall, in the old Marche of Brandenburg, in 1718. His father was a thoemaker. This wonderful man, to -il appearance deftined by his birth to fuperintend a little fchool in an obfcure town of Germany, raifed himfelf to thie office of prefident of antiquities in the Vatican. After having been fiven years profeffor in the college of Sechaufen near Salfuedel, he went into saxony, wiere he refided feven years more, and was libtarian to Count Bunau at Nothenitz. When he left this rlace, 1754 , he went to Drelden, where be formed an acquaintance with the ableft artifts, and particularly with M. Oder, an excellent painter, and one of the
belt draughtmen of the age. In that year ne ajujured Winche. Lutheranifm, and embraced the Roman Catholic religion. In September 1755 , he fet out for [taly, and arrived at Rome in December following. His principa! ubject was :o fee the Vatican library, and to exrmine the ruins of Herculaneurm.

Mr Winckleman carried with him into Italy a fenfe of beauty and art, which led him initantly to admire the mafterpieces of the Vatican, and with which he began to ftudy them. He foon increafed his knowledge; and it was not till after he had thus purified his tafte and conceived an idea of ideal beauty, which led him into the gieateft fecrets of art, that he began to think of the explanation of other monuments, in which his great learning could not fail to diftinguilh him. His erudition enabled him to fill up his principal plan of writing the "Hiltory of Art." In 1756 he planned his "Reltoration of Ancient Statues," and a larger work on the Tafte of the Greek Artifts; and defigned an account of the galleries of Rome and Italy, beginning with a voJume on the Belvidere flatues, in the manner of Richardfon, who, be fays, only rai over Rome. He alfo intended a hiftory of the corruption of tafte in art, the reltoration of ftatues, and an illultration of the obfcure points of mythology. All thefe different eflays led him to his "Hillory of Art," and his "Monumenti Inediti." It mult, however, be confefled, that the firt of thefe works has not all the clearnefs and precifion that might be expected in its general plan and divifion of its parts and objects; but it has enlarged and extended the ideas both of antiquaties and collectors. The defcription of the gems and fulphurs of the Stofch cabinet contributed not a little to extend Mr Winckleman's knowledge. Few perfons have opportunities of contemplating fuch valt collections. The engravings of Lippet and Count Caylus are all that many can artive at. Mr Winckle. man's Monumenti Inediti, of which he had begun the third volume 1767 , feem to have fecured him the efteem of antiquaries. Had he lived, we flould have had a work long wifhed for; a complete collection of the basreliefs dilcovered from the time of Bartoli to the prefent, the greater part of which are in the poffeffion of Cardinal Albani.

When Cardinal Albani fucceeded to the place of librarian of the Vatican, he endeavoured to get a place for the Hebrew language for Winckleman, who refufed a canonry, becaufe he would not take the tonfure. The elector of Saxony gave him, 1761, unfolicited, the place of Counfellor Richter, the direction of the royal cabinet of medals and antiquities at Drefden. Upon the death of the abbe Venuti, 1762, he was appointed prefident of the antiquities of the apoftolic-chamber, with power over all difcoveries and exportations of antiquities and pictures. This is a polt of honour, with an income of 160 fcudi per annum. He had a profpect of the place of prefident of antiquities in the Vatican, going to be created at 16 fcudi per month, and was named correfponding member of the Academy of Inicriptions. The king of Pruffia offered him, by Col. Quintus Icilius, the place of librarian and director of his cabinet of medals and antiquities, void by the death of M. Gautier de la Croze, with a handfome appointment. He made no fcruple of accepting the offer; but when. it came to the pope's ears, he added an appointment out of his own purfe, and kent him at Rome.

\section*{iv I N [ 717 ] W I N}
finchle- ialn Aprilir 63, he left fome to go with M. Cava1納, WบT! ceppi over Germany and Suizedland. When he came 'to Vienna, he was fo pleafed, with the reception he met with, that he made a loneter llay there than he had intended. But, being fuddenly feized with a lecret uncafinefs and extraordinary defire to rcturn to Rome, he fet out for Italy, putting off his vifits to his friends in Germany to a futase opportunity. As he paffed through 'Trielle, he was affafinated, June S. 1768, by a wreteh samed Arcangeli, a native of Campiglio, a town in the teritory of Piftoia, with whom he had made an acquaintance on the road. This mifcreant had been condemned for a robbery to work in fetters four years, and then to be banifhed the Aullrian territories, on an oath never to return. He had obtained a mitigation of one of his fentences, and retired to Venice; but, changing his quarters backwards and forwards, he was fo reduced in circumftances that he at length took up his lodgings at the inn to which the Abbe happened to come. Arcangeli paid fuch affiduous court to him, that he entirely gained his confidence; and having beer. favoured with a fight of the valuable prefents which he had received at Vienna, formed a defign to murder and rob bim: He bought a new tharp knife on purpofe; and as the Abbe (who lad in the mof friendly manner invited him to liome) was fitting down in his chair, early in the morning, he threw a rope over his head, and before he could difengage himfelf, ftabbed him in five different places. The Abbe had fill Itrength to get down to the ground floor, and call for help; and being laid on a bed in the midft of the moft violent pain, he had compofure fufficient to receive the laft facraments, and to make his will, in which he appointed Cardinal Alexander Albani his reffduary legatee, and expired in the afternoon. The murderer was foon after apprehended; and executed on the wheel oppofite the inn, June 26.

Abbé Winckleman was a middle-fized man; he had a very low forehead, fharp nofe, and little black hollow eyes, which gave him an alpest rather gloomy than otherwife. If he had any thing graceful in his phyfiognomy, it was his mouth. A fiery and impetuous difpofition often threw him into extremes. Naturally enthufaftic, he often indulged an extravagant imagination; but as he pofiefed a ftrong and folid judgement, he knew how to give things a jult and intrinfic value. In confequence of this turn of mind, as well as a neglected education, a cautious referve was a quality he little knew. If he was bold in his decifions as an author, he was ftill more to in his converfation, and has often made his friends tremble for his temerity. If ever man knew what friendnip was, that man was Mr Winckleman, who regularly practifed all his duties; and for this reafon he could boalt of having frieuds among perfons of every rank and condition.

WIND is a fenfible avitation of the atmofphere, occafioned by a quantity of air fowing from one place to another. See Meteorology.

Hot Winds. See Samiel.
Wind-Flower. See Anfmony, Botany Indem.
WIND-Mill, kind of mill, the internal parts of which are much the fame with thofe of a water mill: from \$ which, however, it differs, in being moved by the impulle of the wind upon its fails or ranes, which
are to ce confidered as a whicel in axis. Sce MEcut. vics Index.

WiNL-Gage. See Wind-GiAEE.
Wind-Galls. Sec fiarriery Index.
Winit-Gurs. See Ahi-GUN, under Scienee, Ainufements of.

Inflrument for menforing the Arength, velocity, \& c. of the lViND. See Wind-GiGE, ANEMOMETER and ANE. meseopre.

WiNQ-Hatch, in mining, a term ufed to exprefs the place at which the ore is taken out of the mines.

WlivD-Shock, a name given by our farmers to a diftemper to which fruit trees, and fometimes timber trees, are fubject. It is a fort of bruile and thiver throughout the whole fubltance of the tree; but the bark being often not alfected by it, it is not leen on the outfide, while the infide is twithed round, and greatly injured. It is by fome fuppofed to be occafioned by high winds; but othes attribute it to lightning. Thofe trees are mort ufually aflected by it whofe boughs grow more out on one fide than on the other. 'Ihe beft way of preventing this in valuable trees, is to take care in the plantation that they are theltered well, and to cut them frequently in a regular manner while young.

WIND-Taught, in fea language, denotes the fame as fiff in the wind. 'Too much rigging, high mafts, or any thing catching or holding wind aloft, is faid to hold a Chip wind-tanght; by which they mean, that hee ftoops too much in her failing in a liff gale of wind. Again, when a flip rides in a main ftrefs of wind and weather, they ftrike down her top-mafts, and bring her yards down, which elfe would hold too much wind, or be too much dilfended and wind-taught.

WIND-Sails, a fort of wide tube or funnel of canvas, employed to convey a fream of frefh air downward into the lower apartments of a hip.

This machine is ufually extended by large hoops fituated in different parts of its height. It is let down perpendicularly through the hatches, being expanded at the lower end like the bafe of a cone; and having its upper fide open on the fide which is placed to windward, fo as to receive the full current of wind; which entering the cavity, fills the tube, and ruihes downwards into the lower regions of the flip. There ate generally three or four of thefe in our capital ihips of war, which, together with the ventilators, contribute greatly to preferve the health of the crew.

WINDAGE of \(a\) GUN, is the difference between the diameter of the bote and the diameter of the ball.

WINDLASS, a machine ufed for raifing huge weights, as guns, ftones, anchors, \&c.

It is very fimple, conffling only of an axis or roller, fupported horizontally at the two ends by two pieces of wood and a pulley; the two pieces of wood meet at top, being paced diagonally fo as to prop each other; the axis or roller goes through the two pieces, and turns in them. The puiley is faftened at top where the pieces join. Lafly, there are two ttaves or handfpikes which go through the roller, wherehy it is turned, and the rope which comes over the pullcy is wound off and on the fame.

Windlass, in a hip, is an inftument in' finall hipe, placed upon the deck, juft abaft the fore-maft:- It is made of a piece of-timber fix or eight feet fquate, in

Windars form of an axletree, whofo length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the he!p of hand. fpikes put into holes made for that purpofe. This intrument ferves for weighing anchors, or hoifting of any weight in or out of the thip, and will purchale much more than any capfan, and that without aiy danger to thole that heave; 'for if in heaving the windlafs about, any of the handfikes fhould happen to break, the windlats would pall of itcelf.

WINDOW, an aperture or open place in the wall of a houfe to let in the light. See Architecture, \(\mathrm{N}^{\mathrm{o}} 78\).

The word is Welch, uynt dor, fignifying the pafinge for the wind. Window is yet provincially denominated windor in Lancalhire; i. e. quind-door, or the palfage for air, as that for people was peculiarly called the door.

Before the ufe of glafs became general, which was not till towards the end of the 12 th century, the windows in Britain feem generally to have been compofed of paper. Properly prepared with oil, this forms no contemptible defence againft the intrufions of the weather, and makes no incompetent opening for the admiflion of the light. It is fill ufed by our architects for the temporasy windows of unfinifhed houfes, and not unfrequently for the regular ones of our work fhops. But fome of the principal buildings we may reafonably fuppofe to have been windowed in a fuperior naanner. They could, however, be furnifhed merely with lattices of wood or theets of linen, as thele two remained the only furniture of our cathedrals nearly to the eighth century; and the lattices continued in fome of the meaner towns of Lancallire to the 18 th; and in many diftricts of Wales, and many of the adjoining parts of England, are in ufe even to the prefent moment. Thefe feem all to have been fised in frames that were called capfomenta, and now therefore cafoments in Wales and Laricalhire.

VINDSOR, a borough town of Berkfhire, 22 miles weft of London, moft remarkable for the magnificent royal palace or cattle fituated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the garter are inftalled in the royal chapel here. It fends two members to parliament. MT. Long. c. 36. N. Lat. 51.30.

WINDWARD, in the fea language, denoies any* thing towards that point from whence the wind blows, in refpect of a flip: thus windward-tide, is the tide which runs againt the wind.

WINE, an agreeable feirituous liquor, produced by fermentation from thore vegetable fubllances that contain facchariae matter.! A very great number of vegetable fubftances may be made to afford wine, as grapes, currants, mulberries, elders, cherries, apples, pulfe, beans, peas, turnips, radifhes, and even grafs itfelf. Hence, under the clafs of wines or vinous liquars, come not only wines, abfolutely fo called, but allo ale, cyder, \& c.

Chaf: 7 's
chemitrs,
partiv.
fect. \(v\). chap. 6.
Methert of mal:in: ane.

Wine, however, is in a more particular manner appropriated to the lipuor drawn from the fruit of the vine. The procefs of making wine is as follows: When the grapes are ripe, and the faccharine principle is doveloped, they are then preffed, and the juice which llows ont is received in veflels of a proper capacity; in which the fermentation appears; and proceeds in the following

18 I W 1 N
manner: At the cnd of feveral days, and frequenily a ter a few hours, according to the heat of the atmofphere, the nature of the grapes, the quantity of the liquid, and temperature of the place in which the operation is performed, a novement is produced in the liquor, which continually increales; the volume of the fluid increafes; it becomes turbiel and oily; carbonic acid is difengaged, which fills all the unoccupied part of the veffel, and the temperature rifes to the 72.5 th degree. At the ond of feveral days thefe tumultuous motions fubfide, the rafs Falls, the liquid becomes clearer, and is found to be Ictis faccharine, more odorant, and of a red colour, from the reation of the ardent firit upon the colouring matter of pellicle of the grape.

The wine is ufually taken out of the fermenting veffels at the period when all the phenomena of fermentation have fubfided. When the mals is fettled, the colour of the liquor is weil developed, when it has become clear, and its heat has difappeared; it is put into calks, where, by a fecond infenfible fermentation, the wine is claribed, its principles combine more perfectly together, and its tafte and lmell become more and more developed. If this fermentation be ftopped or fuffucated, the gafeous principles are retained, and the wine is brilker, and more of the nature of nult.

It appears, from the interefting experiments of the Marquis de Bullion, that the vinous fermentation does not take place unlefs tartar be prefent.

The caufes of an imperfect fermentation are the fol- Cates of lowing: I. If the heat be too little, the fermentation imperiec? languilhes, the faccharine and oily matters are not futti- iermentaciently elaborated, and the wine is unctuous and fweet. 2. If the faccharine body be not fufficiently abundant, as happens in rainy feafons, the wine is weak, and the mucitage, which predominates, caufes it to become four by it decompofition. 3. If the juice be too watery, concentrated and boiling muft is added. 4. If the faccharine principle be not fufficiently abundant, the defect may be remedied by the addition of fugar. Macquer has proved that excellent wine may be made of verjuice and fugar; and M. de Bullion has made wine at Bellejames, with the verjuice of his vine rows and moitt fugar.

There haje been many difputes to determine whether grapes thould be preffed with the ftalks or without. This depends on the nature of the fruit. When they are highly charged with faccharine and mucilaginous matter, the ftalk corrects the infipidity of the wine by its bitter principle: but when, on the contrary, the juice is not too fweet, the ftalk renders it drier, and wery rough.

The colouring principle of wine is of a refinous na- Colvinns ture, and is contained in the pellicle of the grape; and matter of the Ruid is not coloured until the wine is formed; forwine. until then there is nothing which can diffolve it: and hence it is that white wine may be made of red grapes, when the juice of the grape is exprefled, and the huf: thrown away. If wine be evaporated, the colouring principle remains in the refidue, and may be extrafed by firit of wine. Old rrines lofe their colour; a pellisle being precipitated, which is cither depofited on the fides of the bottles, or falls to the bottom. If wine be expuled to the heat of the fun during the fummer, the colouring matter is detacleed in a pellicle, which falls to the bottom: when the vefiel is opencd, the difcolouring

\section*{W I N [719 ] W I N}

Winc. is more Speedy, and it is effected in two or three days
\(\pm\) nots fermtation plaincd.

5 aredients The different kinds of wincs produced in Europe and
dififerent other parts of the world are many; the principal of them nes.
during the fummer. The wine thus deprived of jis colour is not perceptibly weakened.

The vinous fermentation has been exanined with gicat accuracy by M. Lavoifier. According to him, the vegetable juice of which wine is to be made confilts of oxygen, hydrogen, and carbone, combined with one another in different proportions, fo as to form chiefly water and fugar. The fermentation produces a fepration of the elements, and a new combination of them; a quantity of the oxygen and carbone combine and tly off in the flate of carbonic acid; part of the carbonc, oxygen, and hydrogen, combine firf witheach other, sta dhen all 'ogether, to form alcohol; another part forms acetous acid ; the water fill remains, and at refidumn falls to the botton compoled of the three elcments combined in other proportions. and their qualities are well known: a catalogue of them would ferve no purpofe here. We fhall, however, fubjoin a table of the quantities of the ingredients of the principal kinds from Neumam's Chemifty.

The colour of wine is frequently artificial; a deep red is almof always the effect of artificial additions, as of
the red woods, elder berrics, bilberries, \& \&e. In Franice no fecret is made of thefe practices, the colouring matters being publicly thrown out after they have been ufed.

Wine.

6
It is well known to be a common practice among Adultera-wine-coopurs, inakeepers, atud other dealers in wines, totion of adulterate bad wine in order to conceal its defeets: if, wime. for inftance, the wine be four, they throw into it a quantity of fugar of le d, which entiely takes away the four tatie. For fimilar purpofes alum is often nised with wine. Such fubltances, however, are well known to be extremely pernicious to the human conflitution; it becomes of importance therefure to be able to detect them whenever they happens to be contained in winc. Several chemilts who bave tunned their attention to this fubject, have funnifhed us with tefts for this purpofe.
To dificover lead diffolved in wine, boil together in a To detco pint of water an ounce of quicklime and half an ounce lead in of flour of brimitone; and when the liquor, which will wine. be of a yellow colour, is cold, pour it into a botth, and Wratinn's cork it up for ufe. A few drops of this liquor being (hemicab dropt into a glats of wine or cyder containing lead, will wofut. iii. change the whole into a colour more or lefs brown, ac- p. 37. cording to the quantity of lead which it contains. If the wine be wholly free from lead, it will be rendered turbid by the liquor, but the colour will be rather a dirly white than a black brown.
By this teft, however, iron is alfo precipitated when diffolved in wine, and is apt to be taken for lead; a miltake which has ruined feveral honeft merchants. The following teft is therefore preferable, as not liable to the farme inconvenience.

Take equal parts of calcined oyfter-fhells and crude tnotleer fulphur in fine powder, and put them in a crucible, methods which put into a fire, and raife the heat fuddenly till it has been expofed to a white heat for 15 minutes. Then take it out, let it cool, beat the ingredients to powder, and put them into a well corked bottle. To prepare the telf liquor, put 20 grains of this powder together with 120 grains of cream of tartar, and put them into a flrong bottle, fill it up with water, boil it for an hour, and let it cool. Cork the bottle immediately, and hake it from time to time. After fome hours repore, decant off the clear liquor into an ounce vial, having firf put 22 drops of muriatic acid into each vial. Cork thefe vials accurately with a little wax mixed up with a little turpentine. One part of this liquor, mixed with three parts of fufpected wine, will difcover the prefence of the fmalleft quantity of lead or copper, by a very fenfible black precipitate, and of arfenic by an orange precipi- \%ournaz tate : but will have no effect on iron, if there be ary; de Pbythe prefence of which, however, may be afcertained by fique, adding a little potaft, which will turn the liquor black october if there be any iron. Pure wine remains limpid after 17910 the addition of this liquor \(\ddagger\) :

As this fubject is of importance, we flall add M. State of. Fourcroy's obfervations on the ftate in which lead exits \({ }^{\text {lad }}\) in in wine, and on the methods of difovering its prefence: "Of the difierent principles which compote wine, there was no doubt (hays he) but that acids were the only ones which were capable of diflolving. oxide (caix) of lead. But was it the tartareous acid al ways contained in larger or fimaller quantity in wine, or the acetous acid developed in thofe which have become tharp, and which there is a grcater temptation to fiveeten ? Expe-

\section*{W I N [720] W I N}
rience had proved to me that the acidulous tartrate of potalh, or the cream of tartar, takes oxide of lead from the acetous acid, and a precipitate of tartrate of lead is formed: the pure tartareous acid prepared in Scheele's method produces the fame effect. In order to undertand how the tharp wine which contains thefe two acids can hold the oxide of lead in fulution, I made the experiments which gave me the following refults: I. The acidulous tartrite (erem. tart.) has no fenfible action upon the oxides of lead. 2. The pure tartareous acid has a flight action upon the oxides, and forms on their furface a little tartrite of lead (iartarifed lend), in a white powder. 3. Wine which only contains the tartareous acidule, would not have any action upon the femi-vitrous oxide of lead or litharge. 4. Sharp wine which we attempt to fweeten by this oxide of lead, acts firf upon it by the acctous acid it contains. 5. When this acetite of lead is formed, the tartareous acid precipitates it in the form of tartrite of lead: this is proved by the precipitate which the folution of the ácetite of lead or lugar of lead forms in the wine. 6. But the acetous acid, if it be in large enough quantity, rediffolves the tartrite of lead in the wine jult as diftilled water would. Bergman has pointed out this folution of tartrite of lead in acetous acid for diftinguihing the tartareous falt from the fulfat of lead (vitriol of lend). 7. As this folution of tartrite of lead in the acetous acid is much quicker, and more eafy in tharp wines than in diftilled water and vinegar, it is probable that the caufe of this difference depends upon the citric and malic acids which I have found in wine, and which I fhall take notice of again on another occafion. 8. Litharged wine then, or wine fweetered with lead, contains tartrite diffolved in the a. cetous acid, and perhaps at the fame time in the malic and citric acids.
"It was ncceflary afterwards to know the propertics of this combination. What experience has taught me is as follows: I particularly examined the tartrite of lead and its folution in acetous acic. The tartrite of lead is fcarcely at all foluble in water; it is in the form of powder, or of fmall white grains which have no fenfible tafte; when it is diffolved in vinegar, the vinegar is foftened, its fharpnefs is diminifhed remarkably, and the folution takes a flight fweetifh tafe, much lefs frong than that of the pure acetite of lead. This tafte proves that the union of the tartrite of lead with vinegar is not only a folution like that of falt in water, by which the properties of the falt are not changed, but a combination which gives occafion to new properties. It is a kind of a triole falt, different from thofe we have hither. to known, formed of two acids and of one bafe; whereis the other triple falts deferibed hitherto are compofed of one acid and two bafes. I name this new triple falt nerio-tartrite of lead. The acetous acid adheres to it more than water in a common folution: what is remarkable in this combination is, that the two acids appear to adhere to the bafe with an equal force, although they have a different attraction for it: nothing in neceffary to produce this equilibrium, but to unite firit the oxide of lead with the acid to which it adheres the moft frongly, and afterwards to put this firf compound in contact with the weaker acid.
"It was neceffary, in order to difonver eafy and certain methods of afcertaining the prefence of lead in wine, to cxamine with care the properties and phenomena of
the decompofitions of the aceto-tartrite of lead. Fized alkalies and ammoniac (wolatile alkali) precipitate from this falt an oside of lead, which is of a grayifl white colour; but as they occaron a precipitate in pure wine, they cannot be of any ufe. The fulphuric (vitriofic) acid decompofes the aceto-taruite of lead, and forms with it inflantly fulphate of lead; which being very little foluble, and very heavy, is precipitated. 'The oxalic, or pure faccharine acid, and the acidulous oxalate, or the falt of forrel of the fhops, likewife decom. pofe this falt, and take from it the lead. The oxalate of lead is procipitated in great abundance : thele two acids, the fulphuric and oxalic acids, not producing any precipitate in pure wine, are very proper to thow the prefence of lead in wine. The fulphate and ovalate of lead, when they are precipitated from wine, are coloured, whereas they are very white when they are formed in diftilled water; but their red or brown colour does not prevent us from difcovering them by a very fimple method. If the precipitates be collceted with care, and are cautioully lieated upon a coal with a blow-pipe, they fnoke, become white, exhale vapours, pafs fucceffively through the flates of the red and yellow oxides of lead, and at length are reduced jato metallic globules at the inflant they are perceived to be agitated by a very evident effervefcence: if we ceafe to blow at this inftant, we oblain globules upon the charcoal. In order to this, it is neceffary, however, that the charcoal be folid, and be not cracked, and that we fould not have blowed too Atrongly; otherwife the globules would be abforbed, and would difappear. The fulphate of lead rcquires a longer time to be reduced than the ovalate of the fame metal, and there is a greater hazard of lofing the metallic particles, which, befide, are in fmall quan. tity.
"To thefe two firit proceffes, already fisficiently certain of themfelves, I wifhed to be able to add one which might be capable of pointing out inftantly the prefence of lead, by an appearance belonging exclufirely to this metal, and which might unite to this advantage that of manifetting very fmall quantities of it. Difitled water impregnated with fulphurated hydrogenous gas, or he. patic gas, extricated from folid alkaline fulphurets (iiver's of fulphur) by acids, prefented me with thefe properties. This folution blackens very deeply that of the aceto-tartrite of lead, and renders roboth of this falt in water or in wine very fenfible. The fenfibility of this reactive is fuch, that we may diute litharged wine with a fufficient quantity of water to take away almon entirely the colour of the wine, and this reactive will fill produce a very manifef alteration. The fulphurated water has, befides the advantage not to occafion any change in the wince which do not contain a metallic fublance, and it is not precipitated by the acids of wine, like the folutions of alkaline fulphurets. In order to procure this reactive pure, it is neceflary to prepare it at the inflant of the cxperiment, by receiving in a vial full of ditilled water, and inveried upon a flaclf of a fmall hydro-pncumatic. apparatus, filled with dillilled water, the fulphurated hydrogenous gas, feparated from the folid fulphuret of potah by the fulphunic or muriatic acid, and firtt filtered through water in another vial; when the fecund vial contains the third of its volume of the fulphuated hydregennus gas. the gas is faken Arongly with the water, which fills the two thirds of the rial ; and when the abforption is over, the tef liquor is prepared. This re-active changes very quickly in the air: it is neceflary to make it the moment it is to be employed, and to keep it in a veffel quite full and well corked. If there were any fear that the black colour and the precipitation by the gafeous fulphurated water fhould not be futficient to prove the prefence of lead in fpirituous liquors, I would obferve, that this fear would be diminithed by employing the three re-actives mentioned in this memoir, and by depending only on the correfpondent effects of thefe three re-actives: but all fufpicion would be removed, by reducing the three precipitates by the blow-pipe, and obtaining globules of lead from each of them."

Some years ago, the Academy of Lyons propofed the following prize-queftion: What is the beft method of afcertaining the prefence and the quantity of alum diffolved in wine, efpecially in very deep coloured red wine? The prize was gained by M. J. S. Beraud. From his experiments, it appears that a mixture of lime-water and wine in any proportion whatever, will at the end of 12 or 15 hours furnifh a quantity of cryffals, which may be leparated by filtration, and that thefe cryftals will be eafielt difcovered when the quantities' of wine and lime-water are equal; but that wine containing alum diffolved in it, will not form cryftals when mixed with lime-water, but merely depofits a muddy fediment. To know therefore whether any wine contains alum or not, we have only to mix a fmall quantity of it with lime-water: if crytals are formed, it contains no alum ; if not, it does. Again, if wine contains alum, the refiduum that remains after filtration will, as it dries, fplit into quadrilateral fegments, which will detach themfelves from the paper which contains them; but if the wine contains no alum, the refiduum, after it is dry, will remain united and attached to the paper. If one meafure of wine and two-thirds of a meafure of lime-water depofit cryftals, we are certain that if the wine contains alum, the proportion of that alum to the wine will be lefs than 1 to 1152 ; if, when equal parts of wine and lime-water are mixed, no cryitals be depofited, we may be fure that more than \(\frac{1}{400}\) th part of the mafs of wine confifts of alum.

A great proportion of the wine confumed in this country is brought from Spain and Portugal ; government has always difcouraged the importation of French wines by heavy taxes. We are not fure how far fuch conduct is founded on good policy, as the French wines are confeffedly the beft, and might be the cheapeft ; but fuch is the jealoufy and enmity that has alwrays fubfifted between Britain and France, that both mations have been contented to injure themfelves, provided they could do a greater injury to their neighbours. Befides, the advantages which Britain derives from the Purtugal trade are tery great, and it would not be eafy perhaps to fecure them on any other
to prevent their fretting, which is done by keeping then in the fame degree of heat. In fpring and fall, the wines in Bourdeaux are fubject to changes that may be dangerous, if not prevented by neceffaly rackings: thefe changes are fulcly the eflicts of the lealons. If wines are chilled, and of caurfe turn foul, from being hlipped and landed in culd weather, they will foon recover by putting them in a warm vault, well covered with faw-dufl. As foon as they are in the vault, they ought to be covered up. But if flipped and landed in fummer, if the fmalled degree of fermentation be found on them, it will be requifite to dip the bung cloths in brandy, and leave the bungs loole for fome days, to give it time to cool; and if in a fortnight or three weeks the fermentation do not ceafe, and the winc becume bright, it will be proper to rack it (matchingthe hogheads well with brimftone), and force it with the whites of eight eggs. If it then becomes fine, bung it tight, and let it remain fo until it is bottled. If wines new landed are wanted foon for the bottle, it will be necefiary to force them immediately, and let them remain bunged clofe for at leaft a month, to recuver from the forcing, or if two months the better; for wines bottled in high order come much fooner into drinking than if bottied when Hat, which all wines are after forcing. Wine muft never be bottled the leaft foul, which produces a tendency to fret; and if bottled in this fate, will never come in order, but may poffibly be loft : for this there is no remedy but repeated rackings; and care mult be taken (after tinfing the hogsheads well and drawing them) to burn a good piece of match in them. This cools the wine, and there is no danger of hutting the colour, for it recovers it in a little time : but if it did, it is abfolutely neceffary; for if iwine is fuffered to continue on the fret, it will wear itfelf to nothing. Wines bottled in good order may be fit to drink in fix months; but they ạre not in perfection before twelve : from that to two years they may continue fo; but it would be improper to keep them longer, for wines in general have not the body they had formerly, from the vines being too much forced.

It fometimes happens that wines fcuddy and fubborn will not fall with one or even two forcings. It will then be proper to give them five or fix gallons of good frong wine, and force them with the whites of a dozen eggs, with a tea-fpoonful of fand produced from fawingmarble, or a fmall fpoonful of fine falt. Bottled wine in winter fhould be well covered with faw-duft, and if the vaults are cold and damp, ftrew it deep on the floor; if faw-duft is thrown upon the hngtheads, and their fides are bedded fome inches thick, it will keep them from the fret.

The fame treatment is to be regarded with white wines, except that they require to he higher matched, particularly Mulcat wines ; fuch as Frontignac, Beziers, \&c. which being often fweetened with honey, are very fubject to fret; and thefe only frequent rackings, with a great deal of brimftnne, can cool. Hermitage, from not being fufficiently dried, and poffeffing more richnefs than clarer, is alfo very liable to come on the fret, and will require much the fame treatment as the Mufcat wines. Attention flould be had to botle in fine weather, when the wind is north; but to avoid cold or frofty weather. The months of Aprii and Oatober as: favourable. The beft time to bottle port wine is four \(4 \backslash\) year*

Wine. years after the vintage, and to keep them two years in bottle before you begin to ufe them. When wines are racked, and the lees immediately paffed through flanel bags into clofe-necked jars, and directly bottled, there will be very little lof by rackings, as the wine when fine may ferve for filling up.

When wines are deftined for warm climates, it may be proper to rinfe the hogtheads with brandy; and in bottling many rinfe the bottles and corks with it. Wines that have remained a certain time (three or four months) in a vault, and made lefs or more lee, ought never to be fent into the country without firf racking them, otherwife they may be liable to fret; and if bottled in that flate, may rifk being loft.

Wines which may be ordered for immediate drinking will be forced on the hipping, and in a few weeks after they are landed will be fit for the bottle. The forcings proper for claret are the whites of a dozen egge, beat up with a tea-fpoonful of fine fall, and well worked with a forcing rod. Take care to ufe no bad egg. This is for one hogfhead.

The forcing for white wine is ifinglafs diffolved in wine. One ounce is fufficient for two hogfteads. No falt is to be ufed in forcing the white wines. See Croft on IVTines, \(8 \mathrm{vo}, 1788\).

We fhall infert here the following receipt for making rajifn wine.-To a 20 gallon veffel take 100 pounds of raifins; pick of the ftalks, chop them grofsly, and put them into an open tub more wide than deep. Add two parts in three of the water to them, and let them fland 15 days, flirring them well every day. Then frain and prefs them, putting afide the liquor that runs from them. Add the remainder of the water to the raifins that have thus been preffed, and let it fland upon them one week, frequently flirring them as before. Then prefs off the liquor, and add it to what you firt collectcd; putting both runnings togethcr into your veffel, together with one quart of brandy. To colour it, burn three-fourths of a pound of fugar into a fmall quantity of the liquor, and aud this to the wine. When the liquor in the barrel has done finging, flop the veffel clofe, and let it fland till fit to be bottled. The greater the quantity which the veffel holds, and the longer it is kept in the wood, the better will it be.

As fome of the hints for making wines in Champagne may be ufeful in the manufacture of the wines of this country, we infert the following abridged account of the different procefles that are followed in making white and red champagrie.

Great care is neceflaty for making white wine. The ripeft bunches muft be carefully gathered, freed from sotten, dry, and bruifed grapes, put into large bafkets covered with a cloth to keep them from the fun, carried to the fhade, and kept there till the evening, when they are to be fpeedily prefled. The grapes being laid on the bed of the prefs, they are covered with three or four layers of flat fones, and the prefs turned. Thie juice having run for four or five minutes, the prefs is turned backward, the flones removed, the grapes which have protruded thrufl into the heap, the fones replaced, and the prefs turned again. The juice from three of fuch preffures, which will not require an hour, is put by itfelf for the bell wine into a vat, where it is left all night of fettle.

The next morning this juice is poured off from the
fediment, and put into new well rinfed cafks. In thefe it ferments violently at firtt, but afterwards imperccptibly, till about the end of December it becomes fine, having gone through all the flages of depuration. It is then racked off in dry weather, on a clear frofty day, and fined with ifinglafs. About a pound is fufficient for \(4^{\circ}\) puncheons. The ifnglafs being diffolved is well beaten, diluted with wine taken from the cafk, then poured into it, and the whole well firred by an inffrument introduced at the bung-hole. The wine thus left to fettle ferments flightly again, till it be flopped by the cold weather, or by time. In a month or fix weeks it is racked off again, and has another fining with half the quantity of ifinglafs.

For making red wine, the grapes are gathered with the fame precautions as for making white, taking only the black grapes. Thefe are bruifed in particular vef. fels, by men treading on them with frong wooden fhoes: part of the falks are thrown away, and the muf is left in covered veffels to ferment fufficiently to extract the colouring natter from the pellicles. In fome years, three or four days are fufficient ; in others it requires 10,15 , or even 20. When the fermentation begins, the huiks and ftalks are forced down fo as to be covered with the mult, either by means of ftrong poles furnifhed with crofs pegs, or, which is better, by a couple of Atrong men going into the vat, and well treading and mixing its contents. When the air above the vat ex. tinguifhes a candle, the flalks and hufks rife forcibly, whatever pains be taken frequently to fink them, that the muft may not acquire a difagreeable tafte; the contents of the vat experience a degree of ebullition, and the colouring matter is decompofed. The fermentation mult be made to ftop here, that the wine may not acquire a hard tafte, which even time cannot deftroy.

About the end of December, when the fermentation has ceafed, the wine is racked off from the lees; about the middle of May it is racked off again; the barrels are frefh hooped, and the wine is put into the cellar. When it is to be fent to the confumer, it is racked a third time ; the whites of five or fix frefh eggs are well beaten up in a pint of water, for every puncheon hold. ing 240 bottles. Good red champagne will keep in bottles from fix to twelve years.
\(W_{I N E}-P r e f s\), a machine contrived to fqueeze the juice out of grapes, and confifting of feveral pieces of timber, varioufly difpofed, which compofe three bodies of timber-work, clofely united to the axis, which ferves as a fwing whereby it may be moved by the vice. Of thefe there are different fizes as well as different conffructions; for an account of which, illuftrated by figures, fee Miller's Gardener's Dictionary, atticle WINE. Prefs.

Spirit of WINE, or Alcohol, a name given by chemifts to every ardent fpirit produced by diftillation. See Chemistry Index.

WING, that part of a bird, infect, \&c. whereby it is enabled to fly. See Bird and Ornithoiociy.

Wings, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left fides thereof.
WINTER, one of the four feafons or quarters of the year. See Season, \&c.

Winter commences on the day when the fun's diflance from the zenith of the place is greateft, and ends on the
day when its diftance is at a mean between the greatelt and leat.

Under the equator, the winter as well as other feafons returns twice every year ; but all other places have only one winter in the year: which in the northern hemiTphere begins when the fun is in the tropic of Capricorn, 'and in the fouthern hemifphere when in the tropic of Cancer; fo that all places in the fame hemifphere have their winter at the fume time.

Winter-Berry. See Physalis, Botany Index.
WINYERA, a genes of plants of the clais of polyandria, and in the natural fyftem arranged under the r2th order, Holoracer. See Botany and Materia Medica Index.

WINTON, ANDREW, a Scottifn poct and hiftorian of the \(14^{\text {th }}\) century; but very little is known of his life. He was a canon regular of St Andrews, and was prior of the monaftery of St Serf in the illand of Loch Leven in Kinrofs-fuire; for in the chartulary of the priory of St Andrews there are feveral public inftru. ments of Andrew Winton, as prior of Loch Leven. They are dated between the years 1395 and 1413 , fo that Winton mult have been cotemporary with Barbour, whofe merits are on feveral occafions celebrated by him. Winton is beft known as the author of the Orygynale Croorykill of Scotland. This work was undertaken at the requeft of Sir John Wemyfs, the anceftor of the noble family of that name. It remained negleeted for feveral centuries, but in 1795 a fplendid edition of that part of it relative to Scottith affairs, was publifhed by Mr Macpherfon. The time of Winton's death is unknown; but, as he mentions the death of Robert duke of Albany, which happened in 1420 , the hiftorian mult have been alive at that time.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a finenels anfwerable to the liole it paffed through.

Wires are frequently drawn fo fine as to be wrought along with other threads of filk, wool, flax, \&c.

The metals moft commonly drawn into wite are gold, filver, copper, and iron. Gold-wire is made of cylindrical ingots of filver, covered over with a \(\mathbb{K}\) in of gold, and thus drawn fucceflively through a vaft number of bolec, each fmaller and fmaller, till at latt it is brought to a finencfs execeding that of a lair. That admirable ductility which makes one of the dillinguifhing characters of gold, is nowhere more conficucus than in this gilt wire. A cylinder of 48 ounces of filver, covered with a coat of gold, only weighing one ounce, as Dr Halley informs us, is ufually drawn into a wire, two yards of which weigh no more than one grain; whence 98 yards of the wire weigh no more than 49 grains, and one fingle grain of gold covers the 98 yards; fo that the ten-thoufandth part of a grain is above one-eighth of an inch long.

In \({ }^{1} 7^{84}\), Mr Rofwag of Strafbourg prefented to the board of trade fome gauze made of iron wire, for which he received a reward; and the loom he invented for making it was lodged in the collection of machines at Vaucanson. In 1799 Mr Rochon made others, and coated them with a tranfparent glue, to be fubftituted inttead of horn for fhip lanterns, to be ufed between decks, and in engagements by night. He has fince conceired, that with a thin coating of plafter they
might be employed to preferve hips from fire, and buildings on thore ftill mote eafly; or at leat that they might render the ravages of fire lefs frequen, and lefs tertible. Thefe gauzes might be very ufeful 100 for theatrical decorations, which would not be liable in take fire. Their only inconvenience is their being, fo little flexible; but Mr Rochon does not defpair of means being found by chemiftry to remedy this imperfection, and it was with a view of calling attention to this fubject, that he read a paper on it to the clafs.

Whe of Lapland. The inhabitants of Lapland have a fort of fhining flender fubfance in ufe among them on feveral occalions, which is much of the thick. nefs and appearance of our filver wire, and is therefore called, by thofe who do not examine its flructure or fubfance, Lapland wire. It is made of the fincws of the rein deer, which being carefully feparated in the eating, are, by the women, afier foaking in water and beating, fpun into a fort of thread, of admirable finenefs and Atrength, when wrought to the fmalleft filaments; but when larger, is very flrong, and fit for the purpofes of Atrength and force. Their wire, as it is called, is made of the finett of thefe threads covered with tin. The women do this bufinefs; and the way they take is to mele a piece of tin, and placing at the edge of it a horn, with a hole through it, they draw thefe finewy threads, covered with the tin, through the hole, which prevents their coming ont too thick covered. This drawing is performed with their teeth; and there is a fmall piece of bone placed at the top of the hole, where the wire is made flat; fo that ne always find it rounded on all fides but one, where it is flat.

This wire they ufe in embroidering their clothes, as we do gold and filver; they often fell it to ftrangers, under the notion of its having certain magical virtues.

WISDOM, ufually denotes a ligher and more refined notion of things immediately prefented to the mind, as it were, by intuition, without the affifance of ratiocination.

Sometimes the word is more immediately ufed, in a moral fenfe, for what we call prudence, or difcretion, which confilts in the foundnefs of the judgement, and a conciut anfwerable thereto.

WISDOM of Solomon, one of \(t^{\prime} \cdot \mathrm{e}\) books of the Apocrypha. It abounds with Platonic language, and was probably written after the Cabaliftic philofophy was introduced among the Jews.

WIT, is a qquality of certain thoughts and expreffions, much eafier perceived than defined. According to Mr Locke, wit lies in the affemblage of ideas, and putting thofe together with quicknefs and variety, wherein can be found any refemblance or congruity, thereby to make up pleafant pictares and agreeable vifions to the fancy. Mr Addifon limited this definition confiderably, by oblerving, that every refemblance of ideas does not conflitute wit, but thofe only which produce delight and furprife. Mr Pope defined wit to be a quick conception and an eafy delivery: while, according to a late writer; it confifts in an affunilation of diflant ideas.

The word wit originally fignified wifdom. A avite was anciently a wife man: the wittenagenmt, or Sason parliament, an aflemblage of wife men. So late as the reign of Elizabeth, a man of pregnant wit, of great

Wirs II

Wit. wit, was a man of vaft judgement. We fill fay, in his wits, out of his wits, fo: in or out of found mind. The word, however, is now applied in a more limited fenfe.

Without attempting to expofe the inaccuracy of the definitions above mentioned, or hazarding a definition of our own where fo many eminent men have failed, we fhall endeavour to thow in what true wit confifts.

It is evident that wit excites in the mind an agreeable furprife, and that this is owing entirely to the frange affemblage of related ideas prefented to the mind. This end is effected, 1. By debafing things pompous or fecmingly. grave; 2. By aggrandizing things little or frivolous; 3. By fetting ordinary objects in a particular and ancommon point of view, by means not only remote but apparently contrary. Of fo much confequence are furprife and novelty, that, nothing is more taftelefs, and fometimes difgufting, than a joke that has become flale by frequent repetition. For the fame reafon, even a pun or happy allufion will appear excellent when thrown out extempore in converfation, which would be deemed execrable in print. In like manner, a witty repartee is infinitely more pleafing than a witty attack: for though, in both cales, the thing may be equally new to the reader or hearer, the effect on him is greatly injured, when there is accefs to fuppofe that it may be the flow production of fludy and premeditation. This, however, holds mofl with regard to the inferior tribes of witticifms, of which their readinefs is the beft recommendation.

We fhall illuftrate thefe obfervations by fubjoining a fpecimen or two of each of thefe forts of wit :

Of the firft fort, which confifts in the debafement of things great and eminent, Butler, amongft a thoufand other inftances, hatli given us thofe which follow:

\section*{And now had Phocbus in the lap \\ Of Thetis taken out his nap:}

And, like a lobiter boil'd, the morn
From black to red began to turn.
Hudibras, part ii. canto 2.
Here the low allegorical ftyle of the firt couplet, and the fimile ufed in the fecond, afford us a juft notion of this lowell fpecies, which is diftinguilhed by the name of the ludicrous. Another fpecimen from the fame author you have in thefe lines:

Great on the bench, great in the faddle, That could as well hind o'er as fwaddle, Mighty he was at both of thefe,
And fyl'd of zuar, as well as peace:
So fome rats of amphibious nature,
Are either for the land or water.
Ibid. part i. canto I.
In this coapfe kind of drollery, thofe laughable tranflations or paraphrafes of heroic and other ferious poems, wherein the authors are faid to be traveftied, chiefly abound.

The fecond kind, confifting in the aggrandifement of litule things, which is by far the moft fplendid, and difplays a foaring imagination, thefe lines of Pope mill ferve to illuftrate :

\footnotetext{
As Berccynthia, while her offepring vie
In homage to the mother of the fly,
}

Surveys around her in the blefl:abode, An hundred fons, and every fon a god: Not with lefs glory mighty Dulnefs crown'd, Shall take thro' Grubitrect her triumphant round; And her Parnaffus glancing o'er at once, Behold a hundred fons, and each a dunce.
This whole fimilitude is fpinted. The parent of the celeftials is contrafted by the daughter of night and chaos; heaven by Grubftreet; gods by dunces. Befides, the parody it contains on a beautiful paffage in Virgil adds a particular luttre to it. This fpecies we may term the thrafonical, or the mock-majefic. It affects the moft pompous language, and fonorous phrafeology, as much as the other affects the reverfe, the vileft and mon .grovelling dialect.

To this clals alfo we muft refer the application of grave reflections to mere trifles. For that great and ferious are naturally affociated by the mind, and likewife little and tritling, is fufficiently evinced by the common modes of expreffion on thefe fubjects ufed in every tongue. An appofite inftance of fuch an application we have from Philips:

> My galligankins, that have long withfood The winter's fury and encroaching frofts, By time fubdued, (What will not time fubdue!) An horrid chafm difclofe. Splendid Shilling.

Of the third fpecics of wit, which is by far the moft multifarious, and which refults from what may be called the queernefs or fingularity of the imagery, we fhall give a few fpecimens that will ferve to mark fome of its principal rarieties. To illuftrate all would be impoffible. The firt fhall be where there is an apparent contrariety in the things flee exhibits as connected. This kind of contraft we have in thefe lines of Garth :

> Then Hydrops next appears amongt the throng;
> Bloated and big the flowly fails along:
> But like a mifer in excefs fhe's poor,
> And pines for thirft amiddt her watery fore.

Di/penfary.
A fecond fort is, where the things compared are what with dialecticians would come under the denomination of difparates, being fuch as can be ranked under no common genus. Of this we flatl fubjoin an example from Young:

Health chiefly keeps an Atheift in the dark;
A fever argues better than a Clarke:
Let but the logic in his pulfe decay,
The Grecian he'll renounce, and learn to pray.
Univerfal Paflion.
A third variety in this fpecies fprings from confounding artfully the proper and the metaphorical fenfe of an expreffion. In this way, one will affign as a motive what is difcovered to be perfectly abfurd, when but ever fo little attended to; and yet from the ordinary meaning of the words, hath a fpecious appearance on a fingle glance. Of this kind we have an inflance in the fublequent lines:

While thus the lady talk'd, the knight
'Tun'd th' outfide of his cyes to white,

\section*{As men of inward light are wont}

To turn their optics in upon't.
Hudibrar, patt iii. canto 1.
For whither can they turn their cyes more properly than to the light?

A fourth varicty, much refembling the former, is when the argument or comparifon (for all argument is a kind of comparifon) is founded on the fuppolal of corporeal or prifonal attributes in what is Itrictly not fufceptible of them ; as in this,

But Hudibras gave him a twitch
As quick as lightning in the breech,
Juft in the place where honour's lodg'd,
As wife philofophers have judg'd:
Becaufe a kick in that place more
Hurts honour than deep wounds beforc.
lbid. part ii. canto 3 .
The fifth, and only other variety which we fhall mention, is that which arifes from a relation, not in the things fignified, but in the figns of all relations, no doubt the flighteft. Identity here gives rife to puns and clinches; refemblance to quibbles, cranks, and rhimes: Of thefe it is quite unnecefiary to exhibit fpecimens.

Wit, John de, a celebrated penfioncr of Holland, and one of the greateft politicians of his time, was the fon of Jacob de Wit, burgomafter of Dort, and was born in 1625 . He became well fkilled in civil law, politics, mathematics, and other fciences; and wrote a treatife on the Elements of Curved lines, publimed by Francis Schooten. Having taken his degree of doctor of law, he travelled into foreign courts, where he became efteemed for his genius and prudence. At his return to his native country in 1650 , he became penfionary of Dort, then counfellor-penfionary of Holland and Weft Friefland, intendant and regiller of the fiefs, and keeper of the great feal. He was thus at the head of affairs in Holland; but his oppofition to the reeftablifiment of the office of stadtholder, which he thought a violation of the freedom and independence of the republic, coft him his life, when the prince of Orange's party prevailed. He and his brother Cornelius were affafnated by the populace at the Hague in 1674 , aged 47.

WITCH, a perfon guilty of witcheraft.
WITCHCRAFT, a fupernatural power which perfons werc formerly fuppofed to obtain the poffeffion of by entering into a compact with the devil. They gave themfelves up to him body and foul; and he engaged, that they foould want for nothing, and that he would avenge them upon all their enemies. As foon as the bargain was concluded, the devil delivered to the witch an imp, or familiar fpirit, to be ready at a call, and do whatever it was directed. By the afliflance of this imp and the devil together, the witch, who was almoft always an old woman, was enabled to tranfport herfelf in the air on a broomftick or a fpit to diftant places to attend the meetings of the witches. At thefe meetings the devil always prefided. They were enabled alfo to transform thenifelves into various fhapes, particularly to aflume the forms of cats and hares, in which they mont delighted; to inflict difeafes on whomfoever they
thouglat proper ; and to punifh their enemies in a variety Witcheraff. of ways.

The belief that certain perfons were endowed with fupernatural power, and that they were aflited by invilible fpirits, is very ancient. The fagee of the Romans feem rather to have been forcerers than witches ; indeed the idea of a witch, as above defcribed, could not have been prevalent till after the propagation of Chinlianity, as the heathens had no knowledge of the Chriftian devil.

Witcheraft was univerfally believed in Europe till the 1 Gth century, and even maintained its ground with tolerable firmnefs till the middle of the 17 th. Vaft numbers of reputed witches were convi\&ed and condemned to be burat every year. The methods of difcovering them were various. One was, to weigh the Cuppoled Provincial criminal againft the church bible, which, if the was Cloffory. guilty, would preponderate: another, by making her attempt to fay the Lord's Prayer; this no witch was able to repeat entirely, but would omit fome part or fentence thercof. It is remarkable, that all witches did not hefitate at the fanc place; fome leaving out one part, and fome another. Teats, through which the imps fucked, were indubitable marks of a witch: thefe were always raw, and alfo infenfible; and, if fqueezed, fometimes yielded a drop of blood. A witch could not weep more than threc tears, and that only out of the left eye. This want of tears was, by the witch-finders, and even by fome judges, confidered as a very fubftantial proof of guilt. Swimming a witch was another kind of popular ordeal generally practifed: for this fle was ftripped naked, and crofs-bound, the right thumb to the left toe, and the left thumb to the right toe. Thus prepared, the was thrown into a pond or river, in which, if guilty, fhe could not fink; for laving, by her compact with the devil, renounced the benefit of the water of baptifm, that element, in its turn, renounced her, and refufed to receive her into its bofom. Sir liobert Filiner mentions two others by fire: the firft, by burning the thatch of the houfe of the fufpected witch; the other, burning any animal fuppofed to be bewitched by her, as a hog or ox. Thefe, it was held, would force a witch to confels.

The trial by the ftool was another method ufed for the difcovely of witches. It was thus managed: Having taken the fufpected witch, fhe was placed in the middle of a room upon a ftool or table, crobs-legged, or in fome other uneafy pofture; to which if the fubmitted not, the was then bound with cords: there the was watched, and kept without meat or nleep for the fpace of 24 hours (for, they faid, within that time they Mould fee her imp conse and fuck). A little hole was likewife made in the door for imps to come in at ; and left it fhould come in fome lefs difcernible fhape, they that watched were taught to be ever and anon freceping the room, and, if they faw any fpiders or flies, to kill them: if they could not kill them, then they might be fure they were imps. If witches, under examination or torture, would not confefs, all their apparel was changed, and every hair of their body fhaven off with a Marp razor, left they fhould fecrete magical charms to prevent thcir confefling. Witches were molt apt to confefs on Fridays.

By fuch trials as thefe, and by the accufation of chil-

Witcharaft drent, old women, and fools, were thoufands of unhappy women condemned for witchcraft, and burnt at the flake. In the 18 th vorlume of the Statiftical Accomnt of Scotland there is the trial of two witches, William Cuke and Alifon Dick, in Kirkaldy, in 1636 . The evidence on which they were condemned is abfolutely ridiculous:- ihey were, however, burnt for witchcraft. 'The expences which the town and kirk-feffion were put to on this occafion were as follows:
\begin{tabular}{|c|c|}
\hline \multicolumn{2}{|l|}{In primis.-To Mr James Miller, when} \\
\hline he went to Pieftowne for a man to & \\
\hline try them, \(47^{3}\). & L. 2 \\

\end{tabular}

Summa for the kirk's part L. 17 Io Scots.
The Town's part of expences deburfed extraordinarily upon William Coke and Alifon Dick.

Dr Fersiar,
Mancbefler
Tranf.
\%ol. iii.

For a confiderable time after the inquifition was erefted, the trials of witches (as heretics) were confined to that tribunal ; but the goods of thofe who were condemned being confifcated to the holy office, its minifters were fo active in difcovering forcerers, that the different governments found it neceflary to deprive them of the cognifance of this crime. On the continent, commiflioners were then appointed for the difcovery and conviction of witches, who, though lefs active than the inquifitors, were but too zealous in prolecuting their function. In 1494, Sprenger and Infitor, two perfons employed in this commifion, publified a colleetion of trials, moft of which had come before themfelves, under the title of Malleus Maleficarum: this ferved as a kind of inflitute for their fucceflors.

The firft writers againft witcheraft were figmatized as Atheits, though they only endeavoured to prove the imbecility of the perfons accufed, and the infatuation or the knavery of their accufers. Such were the epithets beflowed by Dr Henry More, and even by Cudworth himfelf. Wierus, the difciple of the celebrated Agrip-
pa, gave rife to the firt great controverly on this fub. Witchorat ject. Lis mafter had taught him humanity; and be endeavoured, but with too feeble a hand, to ftop the bloody proceedings of the judges. Wierus appears to have been a well-difpofed, weak man, with extenfive reading on his fubject, but too narrow-minded to comprehend it thoroughly. He involved himfelf in unfpeakable difficulties, by admitting the action of fupernatural powers in certain difeafes, and in goffeffions, while he denied that witches had any concurrence in them. Thefe appearances (faid he) are illufions of the devil, who perfuades fimple and melancholy perfors that the mifchief he himfelf performs, is done by them, and at their pleafure. He was weak enough to attempt the explanation of every fory alleged by his antagonifts, without queltioning the truth of the facts.

Bodinus, a French lawyer of eminence, who had affifted at feveral trials of witches, wrote againft Wierus, in his Demonomania. He urged the concurrent teltimonies of fufficient wituefles, and the confeflions of the witches themfelves, to eftablifh the exiftence of forcery. Wierus owned that the unhappy perfons believed themfelves to be guilty of the crimes alleged againt them, but that they were deceived by the devil. But what do you make of the witches meetings, cried Bodinus ? The witches (replied his antagonift) are atrabilious. This explanation was fo unfatisfactory that Wierus palled for a magician, whom the devil had furnihned with fpecious arguments to fave others from punifiment. Lerchemer, Godelmann, Ewichius, Ewaldus, and fome others, followed him, notwithttarding this ftigma; but they were oppofed by men of more acutenefs and confiftency than themfelves; by Remigius, who had condemned feveral hundreds of forcerers to the flames; Delrio, whofe book is a complete Corpus Magiæ; Cujas, Eraftus, Scribonius, Camerarius, and a crowd of othcrs.

In this country, while the belief in witheraft was fupported by royal authority (for James I. is univerfally known to have written on demonology) countenanced by Bacon, and generally adopted among the people, only one writer was hardy enough to oppofe it. This was Reginald Scott, who publifhed a collection of importures detected, under the title of Difcoveries of Witchcraft. James ordered the book to be burnt by the common cxecutioner, and the judges continued to burn witches as ufual. During the civil wars, upwards of eighty were hanged in Suffolk, on the accufations of Hopkins the witch-finder. Webfter was the next writer againf witchoraft; but he had a different fate from that of Scott, for moft of his arguments were refuted by Glanville. This very acute writer was induced to publimh his Philofophical Confiderations about Witcheraft, by tis: apprehenfion, that the increafing dimelief of witches and apparitions tended to affect the evidences of teligion, and even of a Deity. In refpect of argument, he was certainly fuperior to his adverfaises; his reafoning is perfpicuous, though formetimes fubtle, refted on the malt fpecious foundations of evidence, and arranged with great fkill.

On the continent, this controverfy feemed alnoof forgotten, till Bekker publimed his Monde Enchantce, in which he denied the exiftence of witches on the Cartefian principle, that the Deity is the fource of all action, confequently actions fo opposite to his nature and attri.. butes cannot be fuppofed to exift. He was anfwered by

Frederick
itchcraff Frederick Foffman, the father of the modern theory and Wilteis. practice of medicine, in his differtation De Diaboli Poten-
\(\underbrace{\text { tia }}\) in Corpora. via in Corpora.

The lateft witchcraft frenzy was in New England, about 1692, when the execution of witches became a calanity nore dreadful than the fword or the peflidence. The accufers became fo daring, that neither civil nor religious authority would have proved a fecurity againgt their attacks, if all the profecutions had not been fuddenly dronped, ard the prifoners fet at liberty. So far did thofe wretches proceed in abfurdity, that a dog was accufed of throwing perfons into fits by looking at them. As foon as the profeculions were ftopped, all reports of witchcraft ceafed.
It would be ridiculous to attempt a ferious refutation of the exiltence of witches; and at prefent, luckily, the tafk is unneceflary. In this country, at leatt, the difcouragement long given to all fuppicion of witchcraft, and the repeal of the ftatutes againit that crime, havc very much weakened, though perhaps they have not entirely eradicated, the perfuafion. On the continent, too, it is evidently on the decline; and notwithflanding the exertions of \(\mathrm{Dr}_{r}\) De Haen, and of the celebrated Lavater, we have little doubt but that in a chort time pofterity will wonder at the credulity of their anceftors. That there ever were witches, is an opinion that cannot for a moment be believed by a thinking man. The actions imputed to them were either abfurd or impoffible; the witneffes by whofe evidence they were condemned, either weak enthufiafts or downright villains: and the confeffions afcribed to the witches themfelves, effects of a diferdered imagination produced by cruel treatment and exceffive watchings. As to the nightly meetings, demonologits themfelves have been obliged to confefs, that they were nothing elfe but unealy dreams, often produced by foporific compofitions. The facts which have been brougbt forward by the advocates for witchcraft bear in their front the moft evident marks of trick and impofture; and this has conftantly been found out whenever thefe facts bave been properly examined. See Sorcery.

WITENA mot, or Witena Gemol, among the Anglo-Saxons, was term which literally fignified the affembly of the wife men; and was applicd to the great council of the nation, of latter days called the parliament.

WITHERS of a Horse, the juncture of the fhoul-der-bones at the bottom of the neck and mane, towards the upper part of the fhoulder.

WITNESS, in \(L a s v\), a perfon who gives evidence in any caufe, and is fworn to fpeak the truth, the whole truth, and nothing but the truth.

Trial by WITNESSES, a fpecies of trial without the intervention of a jury. This is the only method of trial known to the civil law, in which the judge is left to form in his orm brealk his fentence upon the credit of the witneffes examined: but it is very rarely ufed in the Englifh law, which prefers the trial by jury before it in almoft every inftance. Save only that when a widorv brings a writ of dower, and the tenant pleads that the hurband is not dead; this being looked upon as a dilatory plea, is in favour of the widow, and for greater expedition allowed to be tried by witneffes examined before the judges: and fo, faith Finch, fhall no other cafe in our law. But Sir Edward Coke mentions fome
others; as, to try whether the tenant in a real action Witenberg was duly fummoned, or the validity of a challenge to a juror: fo that Finch's obfervation mult be confined to the trial of direct and not collateral iffues.. And in every cafe Sir Edward Coke lays it down, that the affirmative muft be proved by two witneffes at the leaf.

WIT IENBERG, a city of Germany, capital of the circle of Upper Saxony, 50 miles north of Drefden. It is under immediate vaffalage, and the feat of an nulic judicatory, a general fupeintendency, an infuection and confiftory. The town is not large; but is well fortificd, and contains a famous univerfity, in which Melancthon was a profefor. In this place Martin Luther firlt began to preach againft the pope's indulgences; and in the cathedral of All Saints he is faid to have been buried. In the old citadel of this town the an cient Saxon electors ufed to refide. Befides the univerfity, there is a Latin fchool in the town, with fix mafters. The library belonging to the univerfity is faid to be very valuable. In \({ }^{2} 756\) the Pruffians being mafters of the town, deftroyed a part of its fortifications. E. Long. 12. 47. N. Lat. 51.49.

WOAD. See Isatis, Botany Index; fee alfo Dyeing.

The preparation of woad for dyeing, as practifed in France, is minutely defcribed by Aftruc, in his Memoirs for a Natural Hiftory of Languedoc. The plant puts forth at firit five or fix upright leaves, about a foot long and fix inches broad: when thefe hang downwards, and turn yellow, they are fit for gathering : five crops are gathered in one year. The leaves are carried directly to a mill, much refembling the oil or tan mills, and ground into a fmooth pafte. If this procefs was deferred for fome time, they would putrefy, and fend forth an infupportable ftench. The pafte is laid in heaps, preffed clofe and fmooth, and the blackint cruft, which forms on the outfide, reunited if it happens to crack: if this was neglected, little worms would be produced in the cracks, and the woad would lofe a part of its ftrength. After lying for fifteen days, the heaps are opened, the cruft rubbed and mised with the infide, and the matter formed into oval balls, which are preffed clofe and folid in wooden moulds. Thefe are dried upon hurdles : in the fun, they turn black on the outfide; in a clofe place, yellowith, efpecially if the weather be rainy. The dealers in this commodity prefer the firf, though it is faid the workmen find no confiderable difference betwist the two. The good balls are diftinguifhed by their being weighty, of an agreeable fmell, and when rubbed, of a violet colour within. For the ufe of the dyer, thefe balls require a farther preparation : they are beat with wooden mallets, on a brick or tone floor, into a grofs powder; which is heaped up in the midd!e of the room to the height of four feet, a fpace being left for paffing round the lides. The powder, moiftened with water, ferments, grows hot, and throws out a thick fetid fume. It is fhovelled backwards and forwards, and moitened every day for twelve days \(; \cdot\) after which it is ftirred lefs frequently, without watering, and at length made into a heap for the dyer.

WOAHOO, one of the Sandwich ifiands, lying to the north-weft of Morotoi, at the diffance of feren leagues. From the appearance of the northeaft and north-weft parts, it is the fineft ifland of the group. Nothing can esceed the rerdure of the hills, the variety
\(\underbrace{\text { Woahoo. }}\)

* Woahoo of wood and lawn, and rich cultivated valleys, which the whole face of the country difplays. A bay is formed by the north and weft extremities, into which a fine river empties itfelf, through a deep valley; but as the water is brackifi for 200 yards from the entrance, watering in it is not convenient. It contains about 60,000 inhabitants. Lieutenant Hergeft, commander of the Dædalus flore-fhip, who had been fent from England, in 1791, to New South Wales, and thence to the Southern Pacific acean, with a fupply of provifions for the Difcorery floop, Captain Vancouver, then on a voyage of difcovery, was here furprifed and murdered by the natives, together with Mr Gooch, the aftronomer. W. Long. 157.5 I. N. Lat. 21. 43 .

WODEN. See Odin, and Mythology, \({ }^{\circ} 40\).
WODEVILLE, Anthony, earl of Rivers, brother to the queen of Edward IV. was born in the end of \(\mathbf{3 4 2}\), or in the beginning of 1443 . Though one of the moft accomplimed men of his age, very little is known of his private hiftory. He was early and conftantly employed either in the tumults of thofe turbulent times, or in difcharging the duties of fome of the higheft offices of the fate, with which he was invefted. Yet he found leifure to cultivate letters, and to be the author of works which, though of little value now, made fome noife in that age, when learning was at a low ebb in Engiand. Thefe confifted chiefly of tranflations from the French; and his lordnhip and "his printer Caxton, were the firf Englifh wisters who had the pleafure to fee their works publifhed from the prefs. This accomplifhed, brave, and amiable nobleman was treacheroully imprifoned by Richard III. in Pomfret caftle, where, during his confinement, he compofed a fhort poem, which has been preferved by John Rous of Warwick, and breathes, fays Dr Henry, a noble fpirit of pious refignation to his approaching fate. He was beheaded on the 23 d of June 1483 , in the 4 nit year of his age.

WODROW, Robert, a clergyman of the weft of Scotland who lived in the beginning of the I 8th century ; well known as the author of an Ecclefiaftical Hiftory of that kingdom during the latter part of the preceding century. His father, Mr James Wodrow, was a man of learning and piety. He preached occalionally to the perfecuted Prefbyterians, and taught a little academy of their ftudents of philofophy and theology at Glafgow, before the Revolution. About that time he was ordained one of the minifters of that city, continuing his connexion with the acadeny till he was elected profeffor of theology by the univerfity in the year 1692 . He taught with reputation and fuccefs till his death in 1708.

His fon Robert was born in the year 1679 ; his mother being then in the 5 ft year of her age. Her death (though it did not happen till feveral years after), was then fully expected; and his father, obnoxious to a tyrannical government, narrowly efcaped imprifonment, or fomething worfe, by attempting to obtain a laft fhort interview with her. As he paffed the toun guard houle, he was marked, and foon followed by the foldiers into his own houfe, and even into his wife's bed-chamber, where he was concealed. Their officer checked this violence; fent them out of the room, and left the houfe himfelf; placing, however, centinels both within and without, till the birth gould be over. In half an hour after, Mr Wodrow at his wife's fuggeftion, affumed the bounet and great-coat
of the fervant of the phylician then in attendance; and Wutiors. carrying the lantern before him, made an eafy efcape through the midft of the guards. They foon renewed their fearch with marks of irritation, thrufting their fwords into the very bed where the lady lay; who pleafantly defired them to defift, "for the bird (laid ftie) is now flown."

His fon Robert went through the ufual courfe of literary education at Glafgow, entered the univerfity in 1691 ; and profecuted the ftudy of the languages and the different branches of plilofophy, till he became a Atudent of theology under the tuition of his father. He was chofen librarian to the univerfity in the year 1698 , and continued in that office four years. There he began his refearches into every thing connected with the ecclefiaftical hiftory of his country, which he continued to purfue to the end of his life; and alfo imbibed his taftc for medals, infcriptions, and whatever feemed curious or illuftrative of Roman, Celtic, and Britilh antiquities.

He was among the firft in Scotland who attended to the ftudy of natural hiftory. From a great number of letters in his own hand writing, begun about this time, it appears that he was in habits of the utmof intimacy with a felect number of literary gentlemen, animated with the fame ardour of refearch; that they correfponded regularly with one another, made collections of fingular fones, of follils, petrified plants, fithes, \&c. and exchanged what they could fpare from their refpective ftores. Among lis correfpondents were Mr William Nicolfon, archdeacon, afterwards bilhop of Carlifle, and at lafl of Derry, anthor of the Hiftorical Libraries; Mr Edward Lhwyd keeper of the Ahmolean clofet at Oxford; Sir Robert Sibbald, phyfician in Edinburgh, author of a natural hiftory of Scotland, and another of Fife ; Loid Pitmedan; Meffrs James Sutherland, Laughlan Campbell minifter of Campbelton, and others. In a letter to Mr Lhwyd dated Augnit - 700 , Mr Wodrow tells him his manfe was but at a little diftance from a place where they had been lithofcoping together, during a vifit of Mr Lhwyd to Scotland. "My parochial charge (he continues) does not allow me the fame time I had then for thofe fubterranean fludies; but my inclination is equaily ftrong, perhaps flronger. I take it to be one of the beft diverfions from ferious fundy, and in itfelf a great duty, to admire my Maker's works. I have gotten fome flore of fofils here from our marle, limeftone, \&c. and heartily with I had the knowing Mr Lhwyd here to pick out what he wants, and help me to clals a great many fpecies which I know not what to make of." He informs him, in the end of the letter, that he had 500 or 600 fpecies of one thing or another relative to natural hinory.

Mr Wodrow, when he left Glalgow, refided a fhort time in the neighbourhood, in the houfe of a very dillant relation, Sir Maxwell of Nether Pollock, then one of the Scots judges. It being within the bounds of the preibytery of Pailley, he offered himfelf to them for probationary trials, and obtained their licence to preach the gofpel in March 1703 . In the fummer following, the parih of Eaftwood, where Lord Pollock lived, becoming vacant, by the deatls of Mr Matthere Crawford (another Scots hiftorian), a petition, with an unanimous call or invitation from the parill to Mr Wodrow to be their minifter, was prefented to the
＊odrow．preßytery；and they，waving part of the ufual fecond trials，in order to expedite the bufinefs，ordained Mr Wodrow to be minifter of Eaftwood on the 28th of Oc－ tober ェファ3．In this charge he continued to the end of his life．Notwithlaanding lis minifterial duty，he fill found forme time to gratify the early bent of his mind towards natural hiltory，and his curiofity to learn every thing in his power，not only at home，but concerning the natural productions of other countrics，and the opi－ nions，cuftoms，manners，and way of living of their in－ habitants．In his farewell letters to his friends，about to fail to the Scottill fettlement of Darien or to the coalt of Africa，\＆c．he directed their attention and en－ quiries to thefe fubjects；and fomething fimilar he fug． gefted to other livends going to refile in remote places of the Highlands，or even on the continent of Europe． The cullection of his MS．letters bound up in five or fix thick 8 vo volumes，though reaching nearly to the end of his life，feems to confilt only of the firlt draught of his own letters to his friends，not a fingle fcrap is now to be found of their anfwers to him．

After his ordination，however，this worthy man，con－ fidering the duties of his office as his principal and only proper bufinefs，rofe into diftinguilhed reputation and ulefulnefs as a preacher，and was louked upon as one of the firf clergymen in the weft of Scotland．Humble and unambitious of public notice，he was well entitled to it， by his confcientious and exemplary piety，his learning，not only in profeflional，but in other branches of knowledge， his natural good fenfe and folid judgement，his benevo－ lent obliging fpirit to all；his warm attachment to his friends，who formed a wide circle around lim，and efpecially his deep concern for the beft interelts of his people，and active exertions for their inftruction and im－ provement．His weekly fermons were all diftinctly written out in long hand，and even his lectures in flort－ hand．Accuftomed to regular compofition，he had ac－ quired an uncommon facility in it．His countenance and appearance in the pulpit was manly and dignified； his voice clear and commanding，his manner ferious and animated：thefe things，joined with the general preju－ dice in his favour，added to the inprefion of the plain edifying difcourfes he delivered，without papers，to his hearers；and living in the near neighbourhood of Glaf－ gow his little church was often crowded，efpecially when he difpenfed the Lord＇s Supper，confidered in Scolland as the principal religious folemnity．

Yet thefe talents，and this merited popularity which followed them，made little impreflion on his own modeft confcientious mind；for he chofe to continue in the obfcure country parith with which he was futt con－ neeted，refiting all the attempts made by his friends or by frangers to get him tranflated into feveral other more honourable and opulent parifies，who were de－ frous of the beneft of his miniftry，bowever convenient the change might have proved for the education of his family．In the year I712，the magiftrates of Glafgow invited him to be one of the minifters of that city ； and in January 1757，a deputation from the town of Stirling did the fame．On the other hand，the patron， heritors，and elders of his om parifh，ftrenuoufly oppofed the trannation．The prenbytery，who had it in their power to have appointed it，found great difficulties in both cafes on the plea of the majus borum ccclefiee；re－ ferred the decifion in the firt cafe to the fynod，and in

Vol．XX．Part II．
the latt to the commiffion of the General Affembly；and thefe courts thought proper to put no reftraint on the minuller＇s judgement or inclination，as he himelelf was certainly the beft judge of his comparative ufefulnefs in two different fituations．

Mr Wodrow was equally confcientious and affiduous in the bufinefs of the ecclefiallical courts，as in his paro． chial duty．Notwilhttanding his fludous turn，he punc． tually attended the meetings of Iretbytery，Synod，and General Aftembly，when elected，as he utien was，a member of that court ；and alfo the commifions in No－ vember and March，which regularly met during that period of the church．His comnexion with Lord lool． lock made lis journeys to Edinburghs eafy ：and after be began to collect materials for his voluminous hitiory，his pertonal infpection of the public recolds and of the vari－ ous MSS．accumulated in the Edinburgh libraics，made his vifits to that capital frequent and neceffry．

In common with the great body of the Preibyicrians， he had ftrongly imbibed what are called Whig princi－ ples；in other words，he was warmly attached to the conftitutional liberties of the people，as eftablifhed by the revolution fettlement．No wonder！The dreadlul perfecution and oppreffion they had fuffered during the two preceding reigns were ftill freth and galling to their minds：they confidered the elevation of King William to the throne and the Hanover fuccelfion，as the two chief bulwarks raifed \(u p\) by Providence，for the fecurity both of their religion and liberty．＇Jhey trembled at every dark appearance thrcatening to this fecurity，fuch as the death of King William．That cloud，however， was foon diffipated hy the perfeverance of the queen＇s minitters in his views and meafures，and the fplendid victories of Marlborough and his allies over the armies of Louis XIV．But the elevation of the Tory minifiry in the latter part of the queen＇s reign was a fesere trial to the Scottifh Preflyterians，and involved the confcien－ tious part of their clergy in very ferious difficullies and dangers．The oath of abjuration requised at that time from clergymen，and enforced by civil penalties，and even the royal proclamation for a national thankfgiving， after the peace of Utrecht，preffed hard upon the forio－ pulous confciences of many of the clergy．The very language of the oath feemed to them dubious and jefui－ tical，hofile to the elector of Hanover＇s newly acquired light to the crown，conferred on him by the parliament and the people；and as to the other point，they had not freedom to lead their people，in a folemn thank fiving to Heaven for a peace，termed fafe and honourable， which they and the generality of their hearers confider－ ed as dangerous and difgraceful．Mr Wodrow，as mingt be expeitcd，was one of the recufants of the oath：for nothing could move him to flupfle with his confcience．At the fame time the liberality and equity of his mind led him to judge candidly of the confciences of others．Accordingly，he made every effort in his power to reconcile his clenical brethren，and his own people，to fuch of the clergy as had the freedom to take it，and by fo doing，had rendered themfelves obnoxiuus to popular prejudice and odium．With fuch．Lhis good man Atill continned to live，not only in Chriftian，but minifterial communion；endeavouring to foften and re－ move the prejudices againf them，and，in as far as his influence reached，to revive and cherih a fpirit of mu－ tual forbearance．Many propofals he made，and private
meetings

Wodrow. meetings and conferesces he held with his brethren, to prevent their differences from rifing, as they threatened to do, into a fchifm; to prevent them efpecially from entering at all into the church courts; juftly afraid of the fparks of animofity too apt to be kindled there. His endeavours and thofe of his friends were feconded by the prudence of the fuperior courts, efpecially the commiffion of the General Affembly. Whatever paffed there in the way of admonition to the reft of the church, breathed the fpirit of mutual forbearance and love. How he managed the other difficult and delicate point, the Thane \(\sqrt{g} i v i n g\), in a confifency with his duty, does not appear in his letters; nor is it now worth while to inveltigate this as a trait of his character, which might be done, perhaps, from his MS. fermons preached at the time. Only it is pleafing to remark from the letters, that the fame firit of wifdom and mild forbearance which animated the majority of the clergy in the welt, feems alio to have pervaded the officers of the crown, jultices of the peace, and other civil magiftrates in Scotland at the time. The oath was not preffed on the recufants, and the execution of the legal penalties in. curred by the neglect of it avoided; for their general loyalty was undoubted.

A more fevere ftroke was inflicted on their adverfaries by the Tory miniftry in the year 1710 by an act of the Britift parliament which reftored patronage to its former full force. An act of the Scotch parliament paffed after the Revolution had extracted the chief fting of that grievance, by placing the election of the minitter of every parifl in the hands of the landed proprictors, called heritors, in conjunction with the elders, or members of the kirk-feffion. A majority of that joint body, at a meeting appointed for the purpofe, drew up a call or written invitation, which they fubfrribed to a particular candidate to be their miniller. 'This was prefented to the prefluytery of the bounds, the proper judges of his learning and moral character; and if thele were found unesceptionable, he was ordained, or folemnly confecrated and inflalled into the office. This Scotch att having continued in force for twenty years, and being conceived to have become perpetual by the articles of the Union, was now repealed ; and the choice of a minifter to every parilh was in effect placed in the power of a fingle perfon, a patron, becaufe he had in fact the fole power of nominating the only candidate who could enjoy the benefice.

Mr Wodrow was exceedingly averfe from the revival of the power of patronage; and in this he was influenced both by his political and religious principles. In his letters, he feems to have looked upon a patron of a parith, as a kind of hereditary defpot; or at leaft like a prince, who had no reftraints laid on his prerogative, to prevent or check the abufe of it. The paramount power or truft committed to a patron, this confcientious minifler could not reconcile with the apofolical counfels, to commit the keeping of religious truth to Jaihful men, able alfo 10 infruel others. He thought it very improper to leave the choice of a religious inftructor, in the firf infance, to any fingle perfon whatever, efpecially to one generally a Aranger to the circumflances of the parihioners; one who had little knowledge, and therefore little fympathy with them in their religious fentiments and feelings. He was perfuaded that the purpofes of edification, and the peace of the
country, circumfanced as Scotland then was, were Wodrow. much better fecured by the reftraints laid on a patron in the act 1690 , that is, by admitting the two principal bodies of the parilh to a participation with him in his chcice, than by trulling it wholly to himfelf; and he threw out many judicious hints in his letters, and even fchemes or propofals to his brethren, on this difficult and important fubject.

On the other hand, he wifhed nothing to be attempted but in a conftitutional way, in harmony with the civil power. Few men were fo fenfible as he was of the abufes incident to popalar government, either in church or flate, and of the danger of refifing, even unjult and oppreffive laws, in a tumultuous or diforderly manner. The Prefbyterian church, in the outward order or form of it, he viewed as a well regulated republic. He did not confider the people in their individual capacity, as qualified to vote even on the choice of their own minifler. The elders of the parifh he looked upon as the reprefentatives of the people in the ecclefiaftical courts; and their number, in his own congregation, he reflicted to a very few, four or five at moft, fit to affift him in the exercife of church difcipline within the parith. The relt of his feffion were deacons, whofe jurifdiction was confined to the care of the poor, vifiting the fick, and diffributing the bread and wine at the communion, but could not, like the former, be chofen to reprefent the parilh in the prefbytery and fuperior courts. In this fenfe of the neceffity of order and fubordination, he per: fevered to the end of his life. When, contraty to his judgement or vote, an unpopular brother was to be ordained in a parihh within twelve or fifteen miles diftant from Eaftwood, in confequence of a fentence of the General Affembly, to be executed, perhaps with military affiftance; this aged minifter tbought it his duty, regardlefs of perfonal danger or odium, to countenance the young brother, by joining with the reft of the clergy in laying their hands on him, inviting him afterwards to his pulpit, and exerting any influence be bad to cenciliate the irritated minds of that parifh.

The only publication for which the world is indebted to Mr Wodrow, is The Hiftory of the Singular Snfferings of the Church of Scotland during the twenty. eight years immediately preceding the Revolution. It was written at a proper diftance of time from the events it records; and printed at Edinburgh in the year 1721, in two large folio volumes, with two appendixes confifting of copies of the public records, and of many private, fa. mily, and perfonal papers, letters, \&xc. inferted as vouchers of the hiftorical facts. In collecting this great body of information, the author was affifted by his friends, who chearfully feconded his oun almoft incredible indultry and patience of refearch. In confequence of this, the book has more the appearance of a biographical, than of a hiftorical work. It has, however, the form, and all the effentials of a regular hiftory, divided into books, chapters, and fections, with proper margins and indeses; written in a plain, rather too familiar file, unavoidably interfperfed with Scoticifms, yet thefe futficiently intelligible to an Englifh reader. It cxhibits a diftinct fketch of the characters both of the principal fufferers, and of their perfecutors; of the fprings of the perfecution, in the unjultifiable plans and meafures of an arbitrary government; with the motives of the advifers and executors of them. The unfortunate and

\section*{W O D [ \(\left.7 \begin{array}{ll}731\end{array}\right] \quad\) W O D}

Woirntr. innocent fufferers, our author viewed in the light, not of a fet of wild fanatics, as they were called by their contemporarics, and frequently too by later hiltorians; many of them were mont refpectable for their rank in their country, as well as for their talents and virtues; but even thofe in the lower ranks of faciety, our author thought worthy of fome public notice, as confelfors and martyrs in the noble caufe which they had cfpouled, the fupport of the riglats of confcience, and of national liberty.

The fubject of the hithory is the moft melancholy that could be cholen; a long and fevere perfecution of a people, who had been guilty of nothing undutiful to their civil or ecclefiaftical rulers; a feries of open acts of injuflice and tyranny, perpetrated under the colour of lav, and this with fuch an increafing and inercilefs violence, as to fink the ufual fpirit of a free people, and eafily quafl one or two feeble ill-timed attempts to refint their oppreffors. No wonder that the continued vicur of fuch a wretched and melancholy fcene, witlout any thing joyful to interrupt it, fhould give a melancholy tinge to the mind of the writer, eafily communicated to his readers. On the other hand fome things have happily an oppofite tendency. The maf; of biographical intelligence, though it muft be confeffed it is much too voluminous, and too minute for the management of any hithorian what foever, yet furnifhes a variety of anecdotes, which give fome needful relasation or relief to the fympathy of the reader. Thefe indeed are in part the finnple annals of the poor, without the vamih or ealy elegance of polifhed life; but even in this thape they are not deftitute, both of entertainment and inftruction; and then the minutenels in the detail of names, of perfons, places, and other particular circumftances, adds to the imprefion of the facts, by placing their certainly beyond all reafonable doubt.

If faithfully to record paft facts, and tranfinit the knowledge of them to polterity, be the principal daty of a hiforian, this Wodrow has certainly aimed at ; and alfo to reprefs any feelings hoftile to his fidelity and impartiality; in fhort, to come as near as he was able to the motto prefixed to his volumcs, Nec fudio, nec odio. Doubtlefs, like all other men, he had fome political, and many theological prejudices, the laft chiefly imbibed from education, and confirmed by too high a vencrasion for the charackers of our fuft reformers;-prejudices which warped his perfonal opinions and feelings on both fubjects. But he feems to have made a confider. able effort to prevent his party prejudices from warping or perverting his judgement of the truth or falfehood of llubborn hiftorical facts. Nothing almolt oratorial enters into his narratives, though there is room for admiration, and much fcope for jult indignation; no exaggerated encomiums on his friends, or ftrong opprobrious language in fpeaking of his and their enemies, the unprovoked perlecutors of his church. He allows the facts which he has recorded to fpeak for both, and tranfmit to pofterity a memorial to their honour or their infamy.

The chief fault of this hiftorical collection already hinted at, is its minutenefs, and exceffive copioufnefs. The prodigious multitude of facls it embraces, though different from one another in their circumltances, are in other refpects fomewhat fimilar. 'This mult neceffarily accafion fome repetition and fatiety, efpecially to a fati-
dious reader, who has it, however, in his porver to gra- Wodicutify his tafte by felecting what is moft agreeable to it. Neverthelefs a candid :und patient reader can be at no lofs to furm a proper judgement of the principal tranfactions of the period, from the authentic accounts of them before him, to appreciate the true characters of the actors, or of the motives and views from which they acled. And an inquilitive and penetrating reader will be gratified by fecing not a little of the peculiar principles, opinions, fentiments, habits, and mamess of that age, as diftinguilhed from the prefent; and may thus cltimate the gradual progrefs towards much noble and ufeful improvement; and on the other hand, the progrefs towards a very hurtful corruption and degerecracy of manners, which have both taken place during the lat lundred and twenty years.

At the time of its firt publication, the book met with lefs gencral attention than might have been ex. pected in Scotland, and Icarcely any attention in Eng. land, except from profeffed readers. As it came to be more frudied, it was the more valued, except were there was an evident bias on the oppofite fide. Few can be at a lofs to fee why fuch hiftorians as Hume, Macpherfon, and Dalrymple ftoculd neglect or undervalue fuch a book. Our later Scotch billorians, Somerville and Laing, have done it more juftice. In truth, there is a very near coincidence in their ellimates of the characters they draw, and their accounts of the facts they relate, in common with Wodrow. But efpecially our late illufrious patriot Charles Fox, whofe high abilities, uncommon cardour, and fweetnefs of difpofition, almoft remove the fufpected bias of his party firit-Mr Fox has, in the hiforical fragment publifhed fince his death, given a very honourable teftimony to the fidelity and accuracy of our hiftorian. After mentioning the execution of three females, he adds, page \(13^{1 .}\) " To relate all the intlances of cruclty which occured would be endlefs. Bat it may be neceflary to remark, that no hiftorical facts are better afcertained, than the accounts of them which are to be found in Wodrow. In every inflance, where there has been an opportunity of comparing thefe accounts with the records, and other authentic monuments, they appear to be quite correct."

The collection of the matenials for writing the church hiftory from the public records, and many other authentic fources, muit have coft the author a prodigious labour and time. The pecuniary expence incurred was confiderable, and fcarcely refunded from the fale of the book. The only neat profit, he has been heard to fay, which accrued from it, was one or two hundred pounds that he received from the hing, to whom it was dedicated.
'The lat twelve years of Mr Wodrow's life were chiefly occupied in drawing up a biography of the principal perfons concerned in introducing the reformation of religion into Scotland, and fettling the different forms or modes of ccclefiatical government attempted to be eflablinhed there from the beginning to the end of that period, namely from about the year 1560 to 1660 , when the printed hiftory of the fufferings commences. Had it pleafed God to continue his ufeful life till this larger work was finifhed, public curiofity would hare been much gratified; for it contains the lives, not only of John Knox, George Buchanan, and others already well known, but the lives of a great number more, very
learned

\section*{W O D [ 732 ] W O L}

Wodrove learned, ingenious, refpectable, and worthy mein, fcarcely at all known to the literary world; befides a variety of anecdotes naturally entering into fuch a work, illuitrative of the hiftory and the living manners of that age. Happily thefe manufcript lives are flill preferved, all written with his own pen, and fome of the longeft of them copied, probably during his laft long illnels, in a more legible hand. Whatever important or curions information they may contain, they are not fit for the prefs in their prefent fate. They are now depofited in the library of the univerfity of Glafgow.

Befides writing the hiffory and the biography, both extended by himelelf for publication, and two days every week regularly appropriated to his preparation for the pulpit, much of his time mult have been occafionalIy fpent in writing letters, fome of them like differtations, on theological and other literary fubjects; for he correfponded with a very wide circle of acquaintances and friends in Scotland, England, and Ireland, and with a feew on the contiment and in North America.

His conititution in the firlt part of life was robult and ffrong, liis health in general good; but his fucious babits or conflant reading, and efpecially inceffant writing, it is fuppofed, may have brought on the bodily complaint which occafioned his death. In the latter end of the year 1731, a fwelling about the fize of a fmall chefnut appeared on his breaft, near the collar bone. It was on the fame place where a fpark of firc had fallen when he was a child, and had then left a little lump and hardnefs like a large pea. A bout a month after the fwelling began, it had increaled to the fize " of a plumb, and in April 1732 was a large as a man's firt. It was attempted to be removed by caultic; the attempt failed. His body became greally emaciated, and he gradually declined till his death, which happened on the 2 Ift of March 1734 . Supported by the teftimony of a good confcience, joined with the ftrong confolation and wellfounded hope of the gofpel, he bore this long-continued fevere diftrefs with admirable fortitude, unabated piety and refignation; never uttering a murmur, but behaving to his friends who came to fee him, and to all about him, with much eafe and affection; thus leaving, both in the active exertions of a ufeful life, and in lis patient fufferings at the clofe of it, a very edifying example to his family and his flock. The day before his dcath, he gathered his children around his bed, gave each of them his dying blefing, with counfels fuitable to their ages and circumitances; left of all two boys, neither of them four years old, too young to underftand and feel thefe marks of his affection, yet, after the example of the venerable patriarch, Gen. xlviii. 15. even them he drew to him, laid his bands upon their heads, and devoutly prayed, that the God of his fathers, the angel who had redeemed him from all evil, would blefs the lads.

Mr Wodrow was married in the end of 1708 , to Margaret Warner, grand daughter of the reverend Mr William Guthrie of Fenwick, well known in Scotland by his writings, and daughter of the reverend Patrick Warner, then living on his eftate of Ardeer in Ayrfhire. Mr Warner, in the early part of his life, had been chaplain to the Eaft India Company at Madras. After his yeturn home, he was driven from his miniftry and from the kingdom, by the perfecution of the privy council ; but returned in confequence of King James's indulgence, and became minitter of Irvinc. He had a petfonal in-
terview on his laft return with the prince of Orange at the Hague, a fhort time before the Revolution, an account of which appears in the hiftory, vol. ii. p. 604. Mr Wodrow had a family of 16 children, nine of whom, with his widow, furvived him in decent circumflances, without any breach among them for above 25 years. The orly remaining furvivor is the reverend Dr James Wodrow of Steveniton in Ayrhire.

Befides his collection of foffils, and a few Roman and Britifh medals, Mr Wodrow left a valuable library of books, many volumcs of pamphlets and alfo of manufcripts written by others, fent to him in prefents, or copied by his orders. The moft valuable part of them is now in the advocates library, and in the repofitories of the church at Edinburgh. His own manufcript biography, as has been already faid, is in the library of the univerfity of Glafgow.
WOLAW, a town in Germany, in Silefia, and capital of a duchy of the fame name. It is furrounded with ftrong walls and a morafs, and one part of the houfes are built with fone. The cafle is alfo encompaffed with deep ditches, and the greatelt part of the inhabitants are employed in a woollen manufacory. In 1709 a Protefant church was allowed to be built here It is feated on the river Oder, 20 miles north-weft of Breflau, and 32 fouth-caft of Glogau. E. Long. 16. 54. N. Lat. \({ }^{1}\). 18.

Wolf or Woolf Poifon. See Poison.
WOLFE, Maior-general James, was born at Wefterham in the county of Kent, about the beginning of the year 1726 . His father was Lieutenant-general Edward Wolfe. He went into the army when very young; and applying himfelf with unwearied affiduity to the fludy of his profefion, foon became remarkable for his knowledge and his genius. He diltinguifthed himfelf at the battle of Lafelt when little more than 20 , and received the higheft encomiums from the commander in chief. After the peace he fill continued to cultivate the att of war. He contrived to introduce the greateft regularity and the exacteft difcipline into his corpg, and at the fame time to preferve the affection of every foldier. In 1758 he was prefent as a brigadiergeneral at the fiege of Louifoourg. He landed frit on the inland at the head of divifion; and in fite of the violence of the furf, and the force and well directed fire of the enemy, drove them from their poft with great precipitation. The furrender of the town, which happened foon after, was in a great meafure owing to his
 quired during this fiege pointed him out to Mr Pitt, who was then minifter, as the propereft perion to command the army deftined to attack Quebec. This was the mofl difficult and the mof arduous undertaking of the whole war. Qucbec was the capital of the French dominions in North America; it was well fortificd, fituated in the midf of a hoftile country, and defended by an army of \(20,000 \mathrm{men}\), regulars and militia, befides a confiderable number of Indian allics. The troops deffined for this expedition confifted of ten battalions, making up altogether about \(\eta 000\) men. Such was the

\section*{W O L [ 733 ] W O L}
army defined to oppofe three times their own number, defended by fortifications, in a country altogether unknown, and in a late feafon in that climate for military operations. But this little army, fays an ollicer who was prefent at that expedition, and who has been fo obliging as to communicate all the information we defired, was always fanguine of fuccefs; for they were commanded by General Wolfe, who, by a very uncommon magnanimity and noblenefs of behaviour, had attached the troops fo much to his perion, and infpired them with fuch refolution and fleadinels in the execution of their duty, that nothing feemed too difficult for them to accomplith. The admirable fkill with which his meafures were planned, and the prudence and vigour with which they were executed, are well kucwn. He landed lis army on the northern fhore of the river St Lawrence in fpite of the encmy, and forced them to a battle, in which they were completely defeated. The confequence of this battle was the redudion of Quebec, and the conqueft of Canada. In the beginning of the battle General Wolfe was wounded in the wilt by a muket-ball: he wrapt his handkerchief round it, continued to give his orders with his ufual calmefs and perfpicuity, and informed the foldiers that the advanced partics on the front had his orders to retire, and that they needed not be furprifed when it happened. Cowards the end of the battle he received a new wound in the breatt; he immediately retired behind the rearrank fupported by a grenadier, and laid hinfelf down on the ground. Soon after a fhout was heard; and one of the officers who ftood by him exclained, "See how they run !" The dying hero afked with fome emotion, "Who run ?" "The enemy (replied the officer) ; they give way every where." The general then faid, "Pray, do one of you run to Colonel Eurton, and tell him to march Webb's regiment with ali fpeed down to Charles river, to cut off the retreat of the fugitives from the bridge. Now, God be praifed, I flall die happy !" He then turned on his fide, clofed his eyes, and expired.

The death of General Wolfe was a national lofs univerfally lamented. He inherited from nature an animating fervour of fentiment, an intuitive perception, an extenfive capacity, and a paffion for glory, which ftimulated him to acquire every fpecies of military knowledge that itudy could comprehend, that actual fervice could illuitrate and confism. This noble wartath of difuofition feldom fails to call forth and unfold ail the liberal virtues of the foul. Brave above all eftimation of danger ; generouc, gentle, complacent, and humane ; the pattem of the officer, the darling of the foldier. There was a fublimity in his genius which foared above the pitch of ordinary minds; and had his faculties been exercifed to their full extent by opportunity and action, had his judgement been fully matured by age and experience, he would, without doubt, have rivalled in reputation the moft celebrated captains of antiquity. Its body was brought to England, and buried with military honours in Weflminfler abbey, where a roagnificent monument is erefted to his memory.

Wolfe, Chrifian, a celebrated German philofopher, was born at Brellau in \(1679 .^{\circ}\) After having been well inftructed in the rudiments of learning and fcience in his own country, Wolfe profecuted his ftudies fuccellively in the universties of Jena, Hamburgh, and Leipfic. At the age of 26 he hed asquired fo much dininction,
that he was appointed profeffor of mathematics, and foon afterwards of philolophy in general, in the univerfity of Hall. After Leibnitz had publilied his Theorlicea,

Wolre, Wohienbutule. Wolfe, ftruck with the novelty of the edifice which that philofopher had raifed, affiduoufly laboured in the inveftigation of new metapnylical truths. He alfo digeited the Elements of Mathematics in a new method, and attempted an improvement of the art of reafoning, in a treatife On the Powers of the Human Undertand. ing. Upon the foundation of Leibnitz's dactrinc of Monads, he formed a new fyltem of Cofmulogy and Pnemmatology, digefted and demonftrated in a mathe"matical method. Ihis work, entitled Thoughts on God, the World, and the Human Soul, was publified in the year 1719; to which were added, in a fubic-: guent cdition, Heads of Ethics and Policy.

Wolfe was now rifing towards the fummit of philo. Sophical reputation, when the opinion which he enter. tained on the doctrine of neceffity being deemed by his colleagues inimical to religion, and an oration which he delivered in praife of the morality of the Chinefe having given much ofience, an accufation of herefy was publicly brought againt him ; and, though he attempted to juftify himfelf in a treatife which le wrote on the fubject of fatality, a royal mandate was iffued in November I723, requiring him to leave the Pruffian dominions. Having been formerly invited by the landgrave of Hefle-Caftel to fill a profeffor's chair in the univerfity of Caffel, Wolfe now put himfelf under the patronagre of that prince, who had the liberality to afford him a fecure afylum, and appointed him profeffor of mathematics and philolophy. The queltion concerning tho grounds of the cenfure which had been palied upon Wolfe was now every where freely canvaffed; almoft every German univerfity was infamed with difputes on the lubject of liberty and neceflity; and the names of Wolfians and Anti-Wolfians were every uhere heard. After an interval of nine years, the king of Pruflia reverfed his fentence of exile, and appointed him vicechancellor of the univerfity of Hall; where his return was welcomed with every expreftion of triumph. From this time he was employed in completing his Inftitutes of Plilofophy, which he lived to accomplifh in every branch except policy. In IM 45 he was created a baron by the elefor of Bavaria, and fucceeded Ludowig in the office of chancellor of the univerfity. He continued to enjoy thefe honours till the ycar 1754, when he expired. He poffeffed a clear and methodical underflanding; which, by long exercife in mathematical inveftigations, was particularly fitted for the employment of digefting the feveral branches of knowledge into regular fyitems; and his fertile powers of invention enabled him to enrich almofl every field of fcience in which he laboured, with fome valuable additions. The lucid-order which appears in all his writings enables his reader to follow his conceptions with eafe and cer. tainty, through the longelt trains of reafoning.

WOLFENBUTTLE, a confiderabletown of Germany, in the circle of Lower Saxons, and duchy of Prunfwick, with a caltle where the duke of Srunfwick Wolfenbuttle refiles. It is one of the ftrongeft places in Germany, though the fortifications want reparing in feveral places. There is an excellent liorary, kept in a building lately erected for that purpofe, confitting of 116,002 printed bcoks, and \(\$ 020\) meominon books,

Woilrans with a cabinet of curiofities, relating to natural hiffory. It is feated on the river Ocker, five miles fouth of Brunfwick, and 30 weft of Halberfadt. E. Long. 10. 42. N. Lat. 52. 18.

WOLfram, or Tuiciten. See Tungsten, Cifmistry and Mineralogy Index.
WOLFSPERG, a town of Germany, in Lower Carinthia, with a calle, on which the diltrift about it depends, which is 20 miles in length, and 10 in breadth. It is feated on the river Lavand, at the foot of a mountain covered with wood, and full of wolves, from whence the town took its name. It is 36 miles eaft of Clagenfurt. E. Long. 15. O. N. Lat. 46. \(5^{6}\).

WOLGAS' C , a confiderable town of Germany, in the circle of Upper Saxony, and in Pomerania, capital of a territory of the fame name, with a cafle, and one of the beft and largeft harbours on the Baltic fea. It is a well-built place, fubject to Sweden, and fented on the river Pfin. E. Long. 14.4. N. Lat. 54. 1.

WYOLLASTON, WilLiam, defcended of an ancient family in Staffordfhire, was born in 1659 . He was in \(167+\) admitted a penfioner in Sidney college, Cambridge, where, notwithfanding feveral difadvantages, he acquired a great degree of reputation. In 1682, fecing no profpect of preferment, he became affiftant to the head mafter of Birmingham fchool. Some time after, he got a fmall lecture about two miles diffant, but did the duty the whole Sunday; which, together with the bufinefs of a great free-fchool for about four years, begram to break his conflitution. During this face be likewife underwent a great deal of trouble and uneafinefs, in order to extricate two of his brothers from fome inconveniences, to which their own imprudence had fubjected them. In 1688 affairs took a new turn. He found himfelf by a coufin's will entitled to a very ample eftate: and came to London that fame year, where he fettled; choofing a private, retired, and fudious life. Not lons before his death, he publifhed his treatife, entitled The Religion of Nature Delineated; a work for which fo great a demand was made, that more than 10,000 were fold in a very few years. Ife had fearcely completed the publication of it, when he unfortunately broke an arm ; and this alding frength to diftempers that had been growing upon him for fome time, accelerated his death; which happened upon the 2gth of ORober 1724. He was a tender, humane, and in all refpeets worthy 1 man ; but is reprefented to have had fomething of the irafcible in his conftitution and temperament. His Religion of Nature Delineated expofed him to fome cenfure, as if he had put a flight upon Chrifianity, by laying fo much flrefs, as he does in this work, upon the obligations of truth, reafon, and virtue; and by making no mention of revealed religion. But this cenfure mult have been the offspring of ignorance or envy, fince it appears from the introduction to his work, that he intended to treat of revealed religion in a fecond part, which he lived not to finimh.

WOLSEY, Thomas, a famous cardinal and archbifhop of York, is faid to have been the fon of a butcher at Ipfwich. He fludied at Magdalen college, Oxford, where he became aequainted with the learned Erafmus; and in the year 1500 hecame rector of Lymington in Somerfethaire: he was afterwards made chaplain to King Henry V111. and obtained feveral preferments. Having gradually acruired an entire afcendency over
the mind of Henry VIlI. he fucceffircly obtained feveral bilhoprics, and at length was made archbillop of Yoik, lord high-chancellor of England, and prime minifter; and was for feveral years the arbiter of Europe. Iope Lco. X. created him cardinal in 1515 , and made him legatc à latere; and the emperor Charles V. and the French king Francis I. loaded him with favours, in order to gain him over to their inteceft: but after having firft fided with the emperor, he deferted him to efpoufe the intereft of France. As his revenues were immenfe, his pride and offentation were carried to the greateft height. He had 500 fervants; among whom were 9 or 10 lords, 15 knights, and 40 efquires. His ambition to be pope, his pride, bis exactions, and his political delay of Henry's divorce, occafioned his difgrace. In the earlier part of his life he feems to have been licentious in his manners, it was reported, that foon after his preferment to the living of Lymington in Somerfethire, he was put into the flocks by Sir Amias Paulet, a neighbouring jultice of the peace, for getting drunk and making a riot at a fair. This treatment Wolfey did not forget when he arrived at the high flation of lord-chancellor of England; but fummoned his corrector up to London, and, after a fevere reprimand, enjoined him fix years clofe confinement in the Temple. Whatever may have been his faults, there can be no doubt of their having been aggravated both by the zealous reformers and by the creatures of Henry VIII. who was himfelf neither Papift nor Proteftant; for there is every realon to believe that the cardinal was fincere in his religion; and fincerity, or at leaft conffitency, was then a crime. Wolley was the patron of learned men; a judge and munificent encourager of the polite arts; and ought to be confidered as the founder of Chriftchurch college, Oxford; where, as well as in other places, many remains of his magnificent ideas in architecture fill exif. He died in 1530 .

WOMBAT, an animal lately difoovered in Nerw South Wales. See Dasyurus, Mammalia Index.
WOOD, Anthony, an eminent biographer and antiquaian, was the fon of Thomas Wood, bachelor of arts and of the civil lan, and was born at Oxford in 1632. He fludied at Merton college, and in 1635 took the degree of mafter of arts. He wrote, 1, The Hifory and Antiquities of the Univerfity of Oxford; which was afterwards tranflated into Latin by M1r Wafe and Mr Peers, under the title of Hiforia at Antiquitates Univerfitatis Oxonienfis, 2 vols folio. 2. Athence Oxomonfes; or an exact Account of all the Writers and Bifthops who have had their Education in the Univerfity of Oxford, from. the Year 1500 to 1600,2 vols folio; which was greatly enlarged in a fecond edition publified in 1721 by B:fhop Tanner. Upon the fird publication of this work the author was attacked by the univerfity, in defence of Edward earl of Clarendon, lord bigh chancellor of England, and chancellor of the univerfity, and was likewife animadvested upon by Bithop Burnet ; upon which he publifted a Vindication of the IIfforiographer of the Univerfity of Oxford: He died at Oxford in 1695.

\section*{W O O [ 735 〕 W O O}

Nood. WOOD, a fubflance whereof the trunks and branches of trees confilts. It is conmpofed of a number of concentric circles or zones, one of which is formed every year; confequently their number correfponds to the age of the tree. Thefe zones vary in thicknefs according to the degree of vegetation that took place the year of their formation. They are alfo of different degrees of thicknefs in different parts, that part of the tree which is molt expofed to the fun and beft flieltered growing fafteft; bence in this country that part of the zone whicls looked towards the fouth while the tree was growing is generally thickeft. The innermoft circle or zone is the one which was firt formed, the outermoft was formed the year before the tree was cut down. Thefe zones are at firt very foft and tender, and harden by degrees as the tree becomes older: this is the reafon that the middle of a tree is fo often much better wood than the outfide of it.

The proper ligneous part of the wood confirts of longitudinal fibres, difpofed in falciculi, and poffeffed of confiderable hardnefs. It is this longitudinal direction of the fibres that renders it fo much eafier to cleave wood lengthwife, than acrofs the tree, or in any other direction. See Plant and Vegetabye Physiology.

For an account of the ingredients which enter into the compofition of wood, fee Chemistry Index.

For the Method of Staining or Dyeing Wood ree Turning.

For more complete information concerning wood, fee alfo Tree, and Strencith of Materials.

Fofil I' \(^{\prime}\) OOD. Fultil wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different ftrata; fometimes in flone, but more ufually in earth; and formetimes in fmall pieces loofe among the gravel. Thefe, according to the time they have lain in the earth, or the matter they have lain among, are found differently altered from their original hate; fome of them having fuffered very little change; and others being fo highly impregnated with cryftalline, fparry, pyritical, or other extraneous matter, as to appear mere mafles of flone, or lumps of the eommon matter of the pyrites, \&c. of the dimenfions, and, more or lefs, of the internal figure, of the vegetable bodies into the pores of which they have made their way.

The foffil :soods have been arranged by Dr Hill into three kinds: 1. The lefs altered; 2. The pyritical ; and, 3. The petrified.

Of the trees, or parts of them, lefs altered from their original fate, the greateft fore is found in digging to fmall depths in bogs, and among what is called peat or turf earth, a fuftance ufed in many parts of the kingdom for fuel. In digging among this, ufually very near the furface, immenfe quantities of vegetable matter of various kinds are found buried; in fore places there are whole trees farce altercd, except in colour; the oaks in parti- which
cular being ufually turned to a jetty black; the pines as that
and firs, which are allo very ffequetrin, are lest allered, carth.
and are as infam mable as ever, and often contain be- ny, th
tween the bark and wood a black rffin. Large patts fometi
of trees have alfo been not unfrequently met with unal- the co
tered in beds of another kind, and at mucti greater have trees farce altercd, except in colour; the oaks in parti-. which
cular being ufually turned to a jetty black; the pines as that
and firs, which are alloo very ffequetirt, are lefs allered, carth.
and are as inflammable as ever, and often contain be- ny, th
tween the bark and wood a black rffin. Large patts fometi
of trees have alfo been not unfrequently met with unal- the co
tered in beds of another kind, and at muchis greater have trees farce altercd, except in colour; the oaks in parti-. which
cular being ufually turned to a jetty black; the pines as that
and firs, which are alfo very ffequetry, are lefs allered, carth.
and are as inflam mable as ever, and often contain be- ny, th
tween the bark and wood a black rffin. Large patts fometi
of trees have alfo been not unfrequently met with unal- the co
tered in beds of another kind, and at muchis greater have trees farce altercd, except in colour; the oaks in parti- which
cular being ufually turned to a jetty black; the pines as that
and firs, which are allo very ffequetrin, are lest allered, carth.

\section*{W O O [ 736 ] \(\begin{array}{lllll}73 & 0\end{array}\)}

Wiod. Many fubftances, it is certain, have been preferved in the cabinets of collectors, under the title of petrified wood, which have very little right to that name. But where the whole cuter figure of the wood, the exact lineaments of the bark, or the fibrous ard fiftular texture of the ftrix, and the veftiges of the utriculi and trachea or cirveffels, are yet remaining, and the feveral circles yet vifible which denoted the feveral years growth of the tree, none can deny thele fublances to be real fofili wood. See Pftrifiction.

Dr Parry of Bath has recently inveftigated the caufes of the decay of wood, and the means of preventing it. For this purpore he recommends the application of a preparation of the refinous kind, mised with a certain portion of bets-wax. The proportion of the ingredients and the mode of mixing them are as follows: Take 12 ounces of rofin and 8 ounces of roll brimflone, each coarfely pordered, and 3 gallons of train oil; heat them fiowly, gradually adding 4 ounces of bees-wax, cut into frall bits. Frequently fir the liquor, which, as foon as the Colid ingredients are diffolved, will be fit for ule. It is recommended to drefsevery part of the wood. work with this compofition twice over before the parts are put together, and once afterwards; and a higher ftate of prefervation is promifed from its ufe than has Yet been attained. It hould be obferved, that in preparing this varnifh, it is advifable, in order to prevent accidents, to ule an carthen veffel, and to make the fire in the open air.

Wood (fylva), in Ancient Geosraphy, a multitude of trees extended over a large continued tract of land, and propagated without culture. The generality of woods only confif of trees of one kind.--The ancient Saxons had fuch a veneration for woods, that they made them fanctuaries.-It is ordained, that none thall deftroy any wood, by turning it into tillage or pafture, \&c. Where there are two acres or more in quantity, on pain of forfeiting 40 . an acre, by 35 Henry VIII. c. 17 . All woods that are felled at If years growth, are to be preferved from deftruction for eight years; and no cattle put into the ground till five years after the felling thereof, \&c. 13 Eliz. c. 25. The burning of woods or underwood is declared to be felony; alfo thofe perfons that maliciounty cut or foil timber-trees, or any fruit-trees, \&c. Thall be fent to the houfe of correction, there to be kept three months, and whipt once a month.

Woon, Engraving ori, is commonly executed on box; and in many cafes, engravings of this kind are ufed with advantage infead of copperplates. The art of cutting or engraving on wood is of very high antiquity; for Chinefe printing is a fpecimen of it. Even in Europe, if credit be due to Papillon, this art was practifed at a rery remote period; for he mentions eight engravings on wood, entitled, "A reprefentation of the warlike actions of the great and magnanimous Maccdonian king, the bold and valiant Alexander; dedicated, prefented, and humbly offered, to the moll holy father, Pope Honorius IV. by us Alexander Alberic Cunio Chevalier, and Ifabella Cunio, \&xc." 'This anecdote, if true, carrics the art of cutting in wood back to 1284 or 5285 ; for Honorius occupied the papal throne only during thefe two years. But this is not the remoteft period to which fome have carried the art in Europe; for the ufe of feals or fignets being of very high antiquity, they
imagine that the invention of wood-cuts mun be coeval with then. The furpolition is certainly plaufible, but it is not fupported by proof. The earliett impreffion of a vooden-cut, of which there is any certain account, is that of St Chriftopher carrying an infant Jefus through the fea, in which a bermit is feen holding up a lanthorn to fhew him the way; and a peafant, with a fack on his back, climbing a hill, is exhibited in the back ground. The date of this impreftion is 1423 . In the year 1432 was printed at Haerlem, "The hiftory of St John the evangelift and his revelation, reprefented in \(4^{8}\) figures in wood, by Lowrent Janfon Coller;" and, in 1438, Jorg Schappf of Augiburg cut in wood the hiitory of the Apocalypfe, and what was called The poor* mari's bible.

A folio chronicle, publinhed 1493 by Schedal, was adorned with a great number of wooden-cuts by William Plydenwurff and Michael Wolgemut, whofe en. gravings were greatly fuperior to any thing of the kind which had appeared before them. The latter was the preceptor of Albert Durer, whofe admirable performances in this department of art are juftly held in the higheft effeem even at the prefent day.

About this period it became the practice of almont all the German engravers on copper to engrave likewife on wood ; and many of their wood cuts furpafs in beauty the impreflions of their copperplates. Such are the wood-cuts of Albert Aldtorfer, Hirbel Pen, Virgil Sules, Lucas Van Cranach, and Lucas Van Leyden, the friend and imitator of Albert Durer, with feveral others.

The Germans carried this art to a great degree of peifection. Hans or John Holbein, who flourifhed in 1500, engraved the Dance of Death, in a feries of wooden-cuts, which, for the frcedom and delicacy of execution, have fcarcely been equalled, and never furpafted. Italy, France, and Holland, have produced capital arlifts of this kind. Joan. Tornæfium printed a bible at Leyden, in \(\mathbf{1 5 5 4}\), with wooder-cuts of excel lent workmanthip. Chrifopher Jegher of Antwerp, from his eminence in the art, was employed by Rubens to work under his infpection, and he executed feveral picces which are held in much eftimation; they are particularly difinguifhed for boldnefs and Spirit.

The next attempt at improvement in this art was by Hugo da Carpi, to whom is attributed the invention of the chiaro fouro. Carpi was an Italian, and of the 16 th century ; but the Germans claim the invention alfo, and produce in evidence feveral encravings by Mair, a difciple of Martin Schoen, of date 1499. His mode of performing this was very fimple. He firf engraved the fubject upon copper, and finiflied it as much as the artifts of his time ufually did. He then prepared a block of wood, upon which he cut out the extreme lights, and then impreffed it upon the print; by which means a faint tint was added to all the reff of the piece, excepting only in thofe parts where the lights were meant to predominate, which appear on the fpecimens extant to be coloured with white paint. The drawings for this fuecies of engraving were made on tinted paper with a pen, and the lights were drawn upon the paper with white paint.

But these is a material difference between the chiaro fcuro of the old German matters and that of the Italians. Mair and Cranach engraved the outlincs and

\section*{W O O}
\(\Gamma\)
deep fladows upon copper. The impreffion taken in this flate was tinted over by means of a lingle block of wood, with thofe parts hollowed out which were defigned to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, to cut the outline on one bloch of wood, the dark hiadows upon a fecund, and the light thadows, or halftint, upon a third. The firf being impreffed upon the paper, the outlines only appeared: this block being taken away, the fecond was put in its place, and bcing alfo imprefied on the paper; the dark fladows were added to the outlines; and the third block being put in the fame place upon the removal of the fecond, and allo imprefled upon the paper, made the dim tints, when the print was completed. In fome inflances, the number of blocks was increafed, but the operation was flill the fame, the print receiving an impreffion from every black.

In 1698, John Baptift Michel Papillon practifed engraving on wood with much fuccefs, particularly in ornamental foliage and Howers, flells, \&c. In the opinion, however, of fome of the moft eminent artifts, his perfornances are ftiff and cramped. From that period the art of engraving on wood gradually degenerated, and may be faid to have been wholly loft, when it was lately re-invented by Mr Bewick of Newcaftle. This eminent artift was apprentice to Mr Bielby, a refpectable engraver on metal. Mr Bielby, who was accuftomed to employ his apprentices in engraving on wood, was much gratified with the performance of Thomas Bewick, and therefore advifed him to profecute engraving in that line. The advice was followed; and young Bewick inventing tools, even making them with his own hands, and fawing the wood on which he was to work into the requifite thicknefs, proceeded to improve upon his own difcovenies, without affitance or infruction of any kind. When his apprenticelhip expired, he went to London, where the obfcure wood-engravers of the time wibhed to avail themfelves of his abilities, while they were determined to give him no infight into their art. During his apprenticellip, he rectived from the Society for the Encouragement of Arts, \&c. a premium of confiderable value for the beft engraving in wood. The cut which obtained the premium was one of a feries for an edition of Gay's Fables. Having remained fome years in London, he returned to Newcaltle, and entered into copartnerthip with his old mafter; and eftablifhed his reputation as an artif by the publication of his admirable Hiftory of Quadrupeds. This was followed by his Hiltory of Birds, in 2 vols. The greater part of the volume on Quadrupeds, and the whole of the firt volume of the work on Birds, was compofed by Mr Bielby.

John Bewick, brother to Thonas, learned the art of him, and practifed it for feveral years in London with great applaufe. His abilities, however, though refpectable, were not, by the beft judges, deemed fo briiliant as his hrother's; and owing to bad heaith, and the nature of his connection with the book fcllers and others, he feems not to have advanced the art beyond the flage at which he received it. He died, fome years ago, at Newcaftle.

Mr Neshit, who executed the admirable cuts from defigns by Thornton, for an edition of Hudibras, as well as the cuts for editions of Shakefpeare and Thomfan's Seafons, and Mr Anderfon, whofe beautiful cuts

Vol. XX. Part II.
adorn the poem entitled Groze Ifill, have been the moft fuccefstul of Thorans Benick's pupils, who have appeared befure the public as artilts. It appears, that the method practifed by the ancient engravers on wood, whofe works are fill admircd, mult have been different from that of Bewick and his pupils. What that method was feems to be altogether unknown. Papillon, who writes the befl hillory estant of the art, guelfes indeed in what manner the old engravers proceeded to as to give to their works the firit and fieedom for which they are famed; but that his gueffes are erroneous feems evident from the ififfiefs of his own works. The principal characterillic in the inechanical department of the productions of the ancient mallers is the croffing of the black lines, which Papillon has attempted with the greateft awk wardnefs, though it feems to have been accomplifhed by them with to much eafe, that they introduced it at random, even where it could add nothing to the beauty of the piece. In Bewick's method of working, this crofs hatching is fo difficult and unnatural, that it may be confidered as impracticable. Mr Nefbit has indeed introduced formething of it into two or three of his pieces; but fo great was the labour, and fo little the advantage of this improvement, if fuch it can be called, that probably it will not be attempted again.

The engravers of Bewick's fchool work on the and of the wood, which is cut acrofs the trunk of the tree, in piects of the proper thicknefs. As wood-cuts are generally employed in the printer's prefs amidft a form of types, this thicknefs muft be regulated by the beight of the types with which they are to be ufed. The tuvis employed are nearly the fame with thofe ufed in copperplate engraving, being only a little more deep, or lózenge, as engravers call it. They muft bave points of various degrees of finenefs for the different purpofes to which they are applied, fome of them being fo much rounded off at the bottom as to approach to the nature of a goodge, whillt others are in fact little chiffels of various fizes. Thefe chiffels and goodges, to which every artif gives the flape which he deems muf convenient, are held in the hand in a manner fomewhat differnt from the tool of the engraver on copper, it being neceflary to have the power of lifting the chips upwards with eafe. To attempt a defcription of this in writing would be in vain ; but it is eafily acquired, we are told, by practice.

The pupils of the fchool of Bewick confider it as quite improper to feak of his invention as a reviral of the ancient art. Some old prints, it is true, have the appearance of being executed in the fame way witis his; but others have certainly been done by a method very different. It is therefore not fair to appreciate the prefent art by what has been done, but by what may be done; and that remains yet to ke Gewn. The art is in its infancy; and thofe who are difpofed to compare it with the art of engraving on copper, ought to look back to the period when conperplate engraving was of as recent invention as Bewick's method of engraving on wood. Marc Antonio, who engraved under the direction of the great painter Raphael, thought it no mean proof of his proficiency in his art, that be was able to imitate on copperplates the wood-cuts of Albert Durer; and Papillon is bighly indignant that there fhould have been perfons fo very blind as to miftake the copies for the originals. If copper has its ad5 A vantages

Wis?! \(-\)

vantages over wood in point of delicacy and minutenefs, wood has, in its turn, advantages not inferior in regard to ftrength and richnefs. Thofe prints which were executed under the aufpices of Titian and Rubens, will always remain a monument of the firit and vigour natural to wood-engraving; and if there be not found in them all the attention to chiaro fcuro, which the prefent age demands, it muft not be attributed cither to defeet in the art, or to want of abilities in the artiits, but to the tafte of the times when chiaro fcuro was little underttood. It remains for fome enterprifing artirt to thew that the vigour of the ancient art may be attained by the prefent one, and at the fame time to add to thar vigour thofe gradations of frade which are fo much admired in good copperplates. As there feems to be a more perfce, or at leaft a more pleafant black produced by wood than by copperplate printing, and certainly a more perfect white (A), who will fay that any intermediate hade whatever may not be produced by wood-cuts? To attempt this on a frall fcale would indeed be vain, becaufe the lilightelt variation, produced by a little more or lefs ink, or a harder peeflure in printing, beass fuch a proportion to a very fhort line, as muft neceffirily render the attempt abortive.

Wood-engraving, therefore, mult always appear to difadvantage while it is confined to fmall futjects, and will never reach its flation as a fine art, till thofe who are engaged in its cultivation improve upon the difcoveries of one another, and apply to fubjects to which it is properly adapted. As an economical art for illuftrat. ing mechanics, various branches of natural hitory, and other fubjects of fcience, it is too little employed even in its prefent ftate.

The works of Bewick and his pupils, which have hitherio been publifhed, are not numerous. Befides his quadrupeds and birds, the Hudibras, and the cuts for fome editions of Shakefpeare and Thomfon's Seafons, by Neibit, and the Grove Hill by Anderfon, already noticed, there are alfo fome others of lefs note. Goldfmith's Traveller and Deferted Village with elegant plates, are all executed by Thomas Bewick, except one or two which were executed by John; Somerville's Chace by the fame artifts, executed in a flyle of elegance which perhaps has never been furpated; a View of St Nicholas's Church, Newcaftle, 15 inches long, by Mr Neflit, who received for it a fil ver medal from the Soci-ty for the Encouragement of Arts.

WOOD, Rotten, Illumination of. This is a fubject which has often been difcuffed by naturalifts. Spallanzani maintained, that there is a perfect analogy between the illumination of rotten wood, and artificial phofphorus; and he imagines, that in the putrid fermentation, the hydrogen and the carbone of the wood come more cafily in contact with the oxygen of the atmofiphere, hy which combination a flow combution, and the illumination of the wood, is produced; and he thinks that this procefs cannot proceed in the irrefpirable kinds of gafes. Ratten wood alfo, in which the neceflary quantity of hydrogen and carbone is not at the fame time difengaged, docs not obtain the property of illuminating. Mr Corradori, however, objects to this
theory, that the flow combution does not take place according to the above theory, as the wood, at the time when it begins to illuminate, is moftly deprived of its refinous particles, and confequently contains but very little hydrogen and carbone; and it appears to him more probable, that the more it lofes of combullible matter, the more it obtains the property of illuminating. There is, he thinks, a very great difference between this natural and the artificial phofphorus. Mr Humboldt concludes, from his expcriments, that the illumination of rotten wood takes place only when it gets into contact with oxygen ; and when it has loft the property of emitting light in irrefpirable gafes, it recovers it again by expoling it to oxygen gas. Dr Gartner, however, is of opinion, that, according to his experiments, a certain degree of humridity is always requifite, and he thirks that oxygen gas is not quite neceflary though the illumination be increafed by'it. This phenomenon, however, being fo very different from all known proceffes of combuttion, where light is difengaged, Dr Gattner afks, whether it be not more agreeing with the animal procefs of refpiration, than with a true combuftion, or whether the illumination of the wood be prodt:ced by phofphorus and carbone in a proportion hitherto unkuown. Dr Gartner is, on the whole, inclined to think, that it is at prefent impoffible to give a fatisfactory explanation of all the phenomena that occur in this procefs. Beckmamn has made numerous experiments on the illumination of rotten wood, in different gafes and fluids, in order to thow fome light on the ideas of the above naturalifts. The refults of thefe experiments differ in fome points from what the experiments of thofe gentlemen have fliewn, which, however, Beckmann aicribes to the nature of roten wood, as a fubftance that is not always of the fame kind, and has not always an equal degree of putrefaction and humidity. It feems alfo to differ materially from the artificial phofphorus in the following particulars. I. It thines in oxygen gas at a very low temperature. 2. It emits light in all irrefpirable gafes, at leaft for a hort time. 3. In muriatic acid gas its light is fuddenly extinguifhed. 4. It thines in a lefs degree in air ratcfied by the air-pump. 5. According to Mr Corradori, it even flimes in the torricellian vacuum. 6. Its illumination is extingu:fhed in oxygen gas, as well as in other kinds of gares, when they are heated. 7. By its illumination in oxygen gas, carbonic acid gas is produced. 8. One may fuffer the rotten wood to be exlinguithed feveral times, one after another, in irrefpirable gafes, without depriving them of the property of making new pieces of rotten wood fline again. 9. Humidity greatly promotes the illumination, and even feems to be neceffary in producing it. 10. The rotten wood continues to hine under water, oil, and other fluids, and in fome of then its light is cven increafed. All this feems to fhew, that the extinction of rotten wood, in different media, does not immediately depend on a want of oxygen, but rather on a particular change, to which the wood itfelf has been expofed.

Woon Cock. See Scolopax, Ornithology Iridex. IVood-Goal. See Capra, Mammalia Index.

WOOD. WOODMO[E. See Forest Courls. WOODS [OCK, a town of Oxfordihire, in England, pleafantly feated on a rifing ground, and on a rivulct; a well compacted borough-town, and fends two members to parliament ; but is chietly noted for Blenlecim houfe, a fine palace, built in memory of the viclory obtained by the duke of Marlborough over the French and Bavarians in Auguft 1704. It was ercetcd at the public expence, and is one of the nobletl feats in Europe. One of the paffiges to it is over a bridge with one atch, 190 feet in diameter, refembling the Rialto at Venice. 'l he gardens take up 100 acres of ground; and the offices, which are very grand, have room enough to accominodate 300 people. The apartments of the palace are magnificently furnithed ; and the Itaircafes, itatues, paintings, and tapeftry, lurprifingly fine. The town is about half a mile from the palace, having feveral good inns; and a roanufacture of theel chains for watches, and excellent gloves. \(\Lambda\) tteel chain has been made at this place which fold for 1701 . - The population is eftimated at 1300 perfons. It is eight miles north of Oxford, and 60 welt-north-weit of Loncion. W. Long. 1. I5. N. Lat. 51 . \(5^{2}\).

WOODW ARD, Dr Joms, was born in 1665 , and educated at a country fchool, where he learned the Latin and Greek languages, and was afterwards fent to London, where he is faid to have becn put apprentice to a linen-draper: He was not long in that fation, till he became acquainted with Dr Peter Barwick, an eminent phyfician, who took him under his tuition and into his family. Here lie profecuted with great vigour and fuccefs the ftudy of philofoplyy, anatomy, and phyfic. In 1692 , Dr Stillingfleet quitting the place of profeffor of phyfic in Greham college, our author was chofen to fucceed him, and the year following was elested F. R. S. In 1695 he obtained the degree of M. D. by patent from Archbifhop Tennifon; and the fame year he publithed his Effay towards a Natural Hiftory of the Earth. He afterwards wrote many other pieces, which have been well received by the learned wonld. He founded 2 lecture in the univerfity of Cambridge, to be read there upon his Efliy, \&c. and handfomely endowed it. He died in \(17: 8\).

WOOF, among manufafurers, the threads which the weavers fhoot acrofs with an inltrument called the floushe. Sec Cloth.

WOOKEY or OKET Hole, a remarkahle cavern two miles from the city of Wells in Somerfethire; for an account of which, fee the article Grotto.

WOOL, the covering of theep. See Ovis and Sheep.

Wool refembles hair in a great many particulars; but befides its finenefs, which conftitutes an obvious difference, there are other particulars which may ferve allo to difinguifh them from one another. Wuol, like the hair of horfes, cattle, and moft other animals, completes its growth in a year, and then falls off as hair does, and is fucceeded by a frefla crop. It differs from hair, however, in the unitormity of its growth, and the regularity of its fhedding. Every filament of wool feems to keep exact pace with another in the fame part of the body of the animal ; the whole crop fprings un at once; the whole advances uniformly together; the whole loofens from the asin ncarly at the fame period, and thus falls off, if not
previoutly fhorn, leaving the animal covcred witls a finet coat of young wool, which in its turn undergoes the farme regular mutations.

Hairs are commonly of the fame thicknefs in every part; but wool conftantly varies in thicknefs in different parts, being gencrally thicker at the points than at the roots. That part of the fleece of fleep which grows during the winter is finer than what grows in funmer. This was fift obferved by Dr Anderfon, the chitor of the Bee, and publiflied in his Ohfermations on the Mfeans of arciting a Spirit of National Induflry.

While the wool remains in the flate it was firf fhorn off the theep's back, and not forted into its different kinds, it is called flecce. Each flecec confifts of wool of divers qualities and degrees of finenefs, which the dealers therein take care to feparate. The French and Englinh ufually feparate each fleece into three forts, viz. 1. Mother-wool, which is that of the back and reck. 2. The wool of the tails and legs. 3. That of the breaft and under the belly. The Spaniards make the like divifion into thrce forts, which they call prime, focond and third; and for the greater eafe, mark each bale or pack with a capital letter, denoting the fort. If the triage or feparation be well made, in 15 balcs there will be 12 marked \(R\), that is, refine, or prime; two marked \(F\), for fine, or fecond; and one \(S\), for thirds.

The wools moft efteemed are the Enelifh. chiefly thofe about Leominfter, Cotfwold, and the ifle of Wight; the Spanifh, principally thofe about Segovia; and the French, about Berry: which laft are faid to have this peculiar property, that they will knot or bind with any other fort; whereas the reft will only kinot with their own kind.

Among the ancients, the wools of Attica, Megara, Laodicea, Apulia, and efpecially thofe of 'rarentum, Parma, and Altino, were the mofl valued. Varro alfures us, that the people there ufed to clothe their theep with 0 kins, to fecure the wool from being damaged.

Of late a great deal of attention has been paid to wool in this country, as well as feveral others. Several very fpirited attempts have been made to improve it, by introducing fuperior brceds of fheep, and better methods of ranaging them. For this purpofe has been formed the

Britib Wool Society, an aflociation formed for the purpole of obtaining the beft breeds of finc-woolled fhecp, with a view of afcertaining, by actual experiments, how far eacb fpecies or variety is calculated for the climate of Great Britain ; the qualities of their wool refpectively; the ufes to which each kind of wool could be moft profitably employed in different manufactures; and the comparative value of each fpecies of theep, fo far as the farme can be determired.

Attention had for fome time been paid by the Highland Society to a famous breed of fine woolled thecp in Shetland; but it occurred to Sir John Sinclair of Ulbfter, baronet, and to Dr James Anderfon, well known as the autbor of many ureful \(]\) ublications, that the improvement of Britith wool was a matter of too much importance to be entruited to a fociety which is obliged to devote its attention to fuch a variety of ohjects as the general improvement of the Highlands of Scoiland. The latter of thefe gentlemen, therefore, in an Appendix to the Report of the Committee of the Highland

Society of Scotland, for the year 1790 , propofed the plan of a patriotic allociation for the improvemont of Briiifb reool; and the former, who was convener of the committee to whom the fubject of Shetland wool had been referred, wrote circular letters, recommending the plan. The confequence of which was, that on the 31 ft of January 1791, feveral noblemen and gentlemen of the higheit relpectability met in Edinburgh, and constituted themfelves into a Society for the Improvement of Bringb Wool. Of this fociety Sir John Sinclair was elected prefident; after which, in an excellent fpeech, he pointed out to the members the objects of the inftitution, the means by which thofe objects could be attained, and the advantages which would refult from their united labours. This addrefs was afterwards printed by order of the fociety.

The particular breeds of theep to which the fociety propofed to direct its attention, were fheep for the hilly parts of Scotland; theep for the plains, or the Lowland breed; and theep for the illands. They were to try experiments alfo with theep from foreign countries, diftinguifhed by any particular property.

The principal objects which the members had in view, during the firf year of their affociation, were, 1. To collect fpecimens of the belt breeds which Great Britain at that period afforded, in order to afcertain the degree of perfection to which fheep had already been brought in this kingdom. 2. To procure from every country, diftinguifted for the quality of its theep and wool, fpecimens of the different breeds it poffeffed, in order to afcertain how far the original breed, or a mixed breed from it and the native heep of the country, could thrive in Scotland. 3. To difperfe as much as pofible all thefe breeds, both foreign and domeftic, over the whole kingdom, wherever proper perfons could be found to take charge of them, in order to try experiments on a more extenfive fcale than the fociety itfelf could do ; to fpread information, and to excite a fpirit for the improvement of theep and wool in every part of the country.

Sir John Sinclair had previoufly collected a flock, confifting of fleep of the Spanih, Herefordflire, Southdown. Cheviot, Lomond hills, and Shetland breeds, and of a mixed breed from thefe different fheep. This flock amounted to 110 rams, ewes, and lambs. M. d'Aubenton, in confequence of a correfpondence with Sir John Sinclair, fent over to the fociety ten rams and five ewes, of real Spanifin breed, which had been originally entrufted to his care by the late king of France: thele, after encountering a number of obftacles, and after being ftopped and threatened to be nlaughtered at the cuflomhoufe of Brighthelmitone for the ufe of the poor, arrived fafe at Leith. Lord Sheflield, at the fame time, fent to the fociety four rams and fix ewes of the Southdown and Spanifh breeds. Mr Billiton of Kilfall, in Shropllire, prefented them with three Hereford rams, reckoned by many the beft breed in England; the fociety at the fame time ordered 150 ewes of the fame breed, and two ewes of the Long Mountain breed, reckoned the beft in Wales, to be fent along with them. They purchafed 57 rams and 173 ewes of the Cheviot bueed, reckoned the beft in Scotland, for the billy parts of the country. Lord Daer fent them 20 ewes of an excellent breed, which exifted at Mochrum in Galloway. The late carl of Oxford fent them in a prefent
three rams of the Norfolk croffed by the Cape of Good Hope brecd. Mr Jfaac Grant junior of Leghorn, in conjunction with Mr Sibbald, merchant at Leith, prefented them an Apulian ram and ewe; the ram arrived in fafety, but the ewe unfortunately died on the paflage. Mr Baron Seton of Prefton, in Linlithgowflire, fent them a ram and two ewes of a Spanifh breed, which bad been for fome time kept in Sweden unmixed with any other. They purchafed 100 ewes of a fmall breed exitting in the parih of Leuchars in Fife, much refembling the Shetland. The Kight Honourable William Conynghame of Ircland fent them il Spanifh rams, feven Spanith ewes, 15 three-fourth breed and 16 onehalf breed Spanim and Irifh ewes. Lord Sheffield fent them eight rams and 18 ewes; and his Majefty made them a prefent of two rams.

Thus, in the courfe of one year, the fociety acquired by donation or purchafe about 800 fleep of different forts and ages, and many of them from foreign countries : about 500 of thefe were diftributed over different parts of Scotlamd, the greater number of which were fold to gentlemen anxious to promote the views of the fociety, and well qualified to make experiments on the different breeds which they had obtained. The greateft part of the remainder were taken by different gentlemen who kept them for the fociety, and according to their directions, without any expence.

It is impoflible to produce an inftance of fo much having been accomplifhed by a fociety of private individuals in fo fhort a time. Nor was this all; the fame year Mr Andrew Kerr, a very intelligent fheep-farmer on the borders of England, was fent, at the expence of the fociety, to examine the fate of fheep-farming along the eaft coalt of Scotland and the interior parts of the Highlands. His tour was printed by order of the fociety, and contains the firt intimation of the poffibility of the Cheviot breed thriving in the north of Scotland.

In the year 1792 , Meffrs Redhead, Laing, and MarShall, were fent by the fociety, to make a furvey of the ftate of theep-farming through fome of the principal counties of England; the relult of which was alfo pub. liihed by the fociety, and contains more information on the fubject of the different breeds of England than any work hitherto publifhed; and in I794, Mr John Naifmyth was fent on a tour through the fouthern diffricts of Scotland, which completed the circuit of almoft the whole kingdom.

Thus a few private individuals, unaided by the public purfe, had boldnefs enough to undertake afcertaining the comparative value of the different kinds of theep in their own country, and to introduce fome of the mont celebrated breeds of other countries, and fucceeded in the fpirited attempt. It is impolfible in this place to ftate more minutely the various other tranfactions of the fociety; to enter into any detail of the premiums given by this refpectable inftitution for the improvement of the celebrated Shetland breed; or to explain how, as if it were by magic, in a conntry where the manufacture of wool was little known, articles manufactured of that material were made, rivalling, and in forme cales furpafling, the moft celebrated fabrics of other countries. A war having unfortunately arifen, it became impoffible to pay the fame attention, or to carry on with the fame fuccefs, novel enterprifes; even

\section*{W O O [ 74I ] W O R}

Worlambing.
old eftablimments often fall a facrifice amidn the horrors of war. The utmoft that the Britilh Wool Sucicty could expect to do, was to preferve the inftitution in fuch a fate, that when peace ilall be happily reftored it may revive with double energy and firit.

It is a curious fact that the liomans, during their refidence in Britain, eftablifhed a manufactory of woollen cloth at Winchefter, which was fo extenfive as to fupply their army ; and there is realon to believe that the trade which they introduced into Britain, was not neglected by the native inhabitants, for the firlt 900 years of the Cbriftian era. The long Spanith wool was imported into this country fo early as the i 2 th century, and we find that fince the days of Edward IIl. Britinn Heeces were admirably adapted to the kind of cloth which was in greateft requeft, though now they are generally unequal to the production of that which is fought after.

WooL-Combing, a well known operation, which, when performed by the hand, is laborious, tedious, and expenfive. The expence of it through all England has been calculated at no lefs a fum than 800,000l.; and to leffen this expence, the Rev. Edmund Cartwright of Doncafter in Yorklhire bethought himfelf, fome years ago, of carding wool by machinery. After repeated attempts and improvements, for which he took out three patents, he found that wool can be combed in perfection by machinery, of which he gives the following defcription.
Plate
Fig. 1. is the crank lather. A is a tubo through which the material, being formed into a liver, and flightly twifted, is drawn forward by the delivering rollers; \(B\), a wheel faft upon the crofs bar of the crank; C , a wheel, on the oppofite end of whofe axis is a pinion working in a wheel upon the axis of one of the delivering rollers.

Note. When two or more flivers are required, the cans or bakets, in which they are contained, are placed upon a table under the lather (as reprefented at D), which, by having a flow motion, twifts them together as they go up.

Fig. 2. is the circular clearing comb, for giving work in the head, carried in a frame by tro cranks. Fig. 3. the comb-table, having the teeth pointing towards the centre, moved by cogs upon the rim, and carried round upon trucks like the head of a windmill. \(a, b\), The drawing rollers. \(c, d\), Callendar, or conducting rollers.

Note. Underneath the table is another pair of rollers, for drawing out the backings.

In the above fpecification, we have omitted the frame in which the machine ftands, the whecls, flatts, \&c. Had thefe been introduced, the drawing would bave been crowded and confufed; befides, as matters of information, they would have been unncceffary, every mechanic, when he knows the principles of a machine, being competent to apply the movements to it.

The wool, if for particularly nice work, goes through three operations, otherwife two are fufficient : the firf operation opens the wool, and makes it connect together into a rough lliver, but does not clear it. The clearing is performed by the fecond, and, if neceliary, a third operation. A fet of machinery, confifing of three machines, will require the attendance of an overlooker and ten children, and will comb a pack, or 2401 b , in twelve hours. As neither fire nor oil is necelfary for
machine combing, the faving of thofe articles, even the fire alone, will, in general, pay the wages of the overlooker and children; fo that the actual faving to the manufacturer is the whole of what the cembing cofts,

Kocicombing Worcefter. by the old imperfect mode of hand-combing. Machinecombed wool is better, efpecially for machine-fpinning, by at leaft 12 per cent. being all equally mixed, and the flivers uniform, and of any required length.

WOOL.S"ION, 'I'Homas, an Englifh divine, was born at Northampton in 1669 , and educated at Cansbridge. His firft appearance in the learned world was in 1705, in a work entitled, The Old \(\Lambda\) pology for the 'l'ruth of the Cliriftian lieligion, againtt the Jews and Gentileb, sevived. He afterwards wrote many pieces: but what made the molt noife, were his fix Difcourfes on the Miracles of Clirift; which occafioned a great number of books and pamphlets upon the fubject, and raifed a profecution againft him. At his trial in Guildhall, before the lord chief-juftice laymond, he fpoke feveral times himfelf; and urged, that " he thought it very hard that he fhould be tried by a fet of men who, though otherwife very learned and worthy perfons, were no more judges of the fubjects on which he wrote, than himfelf was a judge of the molt crabbed points of the lsw." He was fentenced to a year's imprifonment, and to pay a fine of rool. He purchafed the liberty of the rules of the King's bench, where he continued after the expiration of the year, bcing unable to pay the fine. The greateft obftruction to his deliverance from confinement was, the obligation of giving fecurity not to offend by any future writings, he being refolved to write again as freely as before. Whilft fome fuppofed that this author wrote with the fettled intention of fubverting Chriftianity under the pretence of defending it, others believed him difordered in his mind; and many circumftances concurred which gave countenance to this opinion. He died, January 27. 1732-3, after an illnefs of four days; and, a few minutes before his death, uttered thefe words: "This is a ftruggle which all men mult go through, and which I bear not only patiently, but with willinernefs." His body was intered in SL Gcorge's chu:ch-vard, Southwark.

WOOLWICH, a town in Kent, with a market on Fridays, but no tair. It is feated on the river 'Thames, and of great note for its fine docks and yard, where men of war are built; as alfo for its raft magazines of great guns, mortars, bombs, carnon-balis, powder, and other warlike ftores. It has jiketrife an academy, where the mathematics are tauglt, and young oficers inftructed in the military art. It is nine miles eaft of London. E. Long. O. 10. N. Lat. 5 I. 30.

WORCESTER, in Latin Wigornia, the capital of a county of England of the fame name, faunds on the river Severn, but fo low that it can hardly be feen till one is clofe upon it. It is fuppofed to be the Branonium of Antoninus, the Branogenium of Ptolemy, and to have been built by the Romans to awe the Britons on the other fide of the Severn. It was made an epircopal fee about the year 680 by Sexulphus bihop of the Mercians; but the prefent cathedral was begun by Wulfon in the year 1084. The town bath been leve. ral times burnt down; firf, in 104r, by Hardicanute, who alfo mafiacred the citizens; fecondly, not long after William Rufus's time; and a third time, when King Stcphen befieged and took it. Here, in latter times,

\section*{W O R [ 742\(] \quad W 0\) R}

WrorceRer. was fought that battle, in which Charles II. with his Scots army, was defealed by Cromwell. In a garden, near the louth gate of the city, where the action was hotten, the bones of the flain are oflen dug up. It had formerly frong walls and a callle; but thefe have been demolithed long ago. It is now a large city, the fireets broad and well paved, and fone of them very regular and well built, particularly Foregatefltrect; fo that in general it is a very agreeable place. The cathedral is a fately edifice, and among other monuments in it are thofe of King John, of Arthur, elder brother to Henry VilI. and of the countefs of Salifbury, who gave occalion to the inftitution of the order of the Garter. There are feven or eight holpitals in and about the city; of which that built and endowed by Robert Berkley of Spetchley, Efq. is a very noble one. There is a fchool founded by Henry VIlI, three other fchools, and fix charity-fchools. 'The guildhall and the workhoufe are fately flructures. The churches, St Nicholas and All-Saints, have been lately rebuilt, and are very handfome edifices. The city carries on a great trade; for which it is chiefly indebted to its fituation upon the Severn. A prodigious number of people are employed in and about it in the manufactupe of broad-cloth and gloves. The Welch inhabit a part of it, and fpeak their own language. Its market is well fupplied with provifions, corn, and cattle, and its quay is much frequented by thips. By a charter from James I. it is governed by a mayor, fix aldermen, who are jultices of the peace, and chofen out of 24 capital citizens; a fheriff, the city being a county of itfelf; a common council, confinting of 48 other citizens, out of which two chamberlains are yearly chofen; a recorder, town-clerk, two coroners, a fword-bearer, I3 conftables, and four ferjeants at mace. Of the bihops of this fee, there have been, it is faid, one pope, four faints, feven lord high-chancellors, II archbithops, two lord treafurers, one chancellor to the queen, one lord prefident of Wales, and one vice-prefident. The city at prefent gives title of earl and marquis to the duke of Beaufort. W. Long. 1. 55 . N. Lat. 52. 10.

Worcester, Edward Somerfet, AIarquis of, was a diffinguibed political character in the time of Charles I. by whom he was created eatl of Glamorgan, while heirapparent to the marquis of Worcelter. This nobleman flourihed chiefly in the reign of Charles I. and feems to have been a moft zealons adherent to the caufe of that unfortunate monarch, on whofe account it is faid that he and his father wafled an immenfe fum. Of this the king was fo fenfible, that he granted to the earl a moft extraordinary patent, the chief powers of which were, to make him generaliffimo of three armies, and admiral with nomination of his officers; to enable him to raife money by felling his majetly's woods, wardhips, cuftoms, and prerogatives; and to create by blank patents, to be filled up at Glamorgan's pleafure, from the rank of narquis to baronet. If any thing, fays Lord Orford, could ju tify the delegation of fuch authority, befides his majelly having lof all authority, when he conferred it, it was the promife wilh which the king concluded of beffowing the princefs Elizabeth on Glamorgan's fon. This patent was given up by the marquis to the houfe of peers after the reftoration. He died not long afles that era, in \(\mathbf{1} 667\), after he had publified what Lord Orford calls the following amazing piece of folly.
"A century of the names and fantlings of fuch in. Worcence. ventions, as at prefent I can call to mind to have tried and peefected, which (my former notes being loft) I have, at the initance of a powerful friend, endeavoured now in the year 1655 , to fet thefe down in fuch a way as may futficiently inftuct me to put any of them in practice."

Some of the inventions referred to in this work are the following. \(\Lambda\) hip-deilroying engine, a conch-thopping engine, a balance waier-work, a bucket fountain, an ebbing and llowing cafle clock, a tinder-box piftol, a pocket ladder, a mof admirable way to raife weights, a itupendous water-wots. For the latt contrivance the marquis procured an aft of parliament in 1663 , for the fole benefit arifing fiom it, one-tenth of it being appropriated to Charles 11. and his fucceffors.

In a manufcript addition to a copy of the Century of Inventions, the flupendous or water-commanding engine is defcribed as boundlefs for height or quantity, req̧uiring no external, or even additional help or force to be fet or continued in motion, but what intrinfically is afforded from its own operation, nor yet the twentieth part thereof, and the enginc confifteth of the following particulars. 1. A perfect counterpoife for what quantity foever of water. 2. A perfect countervail for what height foever it is to be brought unto. 3. A primum mobile, commanding both height and quantity, regula-tor-wife. 4. A vicegerent or countervail, fupplying the place, and performing the full force of man, wind, bealt, or mill. 5. A helm or ftern, with bit and reins, wherewith any child may guide, order, and controul the whole operation. 6. A particular magazine for water, according to the intended quantity or height of water. 7. A place for the original fountain, or even river to run into, and naturally of its own accord incorporate itfelf with the riling water, and at the very bottom of the fame aqueduct, though never fo big o: high.

Various and very oppofite opinions have been held w:th regard to the title of this nobleman to be confider. ed as a mechanical genius. Lord Ouford bas pronounced his work an amazing piece of folly; and Mr Hume, fpeaking of his political conduct, fays, " that the king judged aright of this nobleman's character, appears from his Century of Arts, or Scantling of Inventions, which is a ridiculous compound of lies, chimeras, and impombilities, and hows what might be expected from fuch a man." Hill. of England. It may be fairly prefumed from the quotations now made, that neither Lord Orford nor Mr Hume was qualified to judge of the marquis's work, otherwife a more temperate or a more modified opinion would have been given. By others, the author of the inventions has been regarded as one of the greateft mechanical geniufes, and is to be confidered as the inventor of the feam-engine, which he denominates a flupendous water-work. There feems to be no reafon to fuppofe that any feam-engine was erected by the marquis himfelf; but it is faid that Captain Savary, after reading the marquis's books, tried many experiments upon the power and force of feam, and at laft fell upon a method of applying it to raife water; and having bought up and deftroyed all the marquis's books that could be got, claimed the honolir of the invention to himfelf, and obtained a patcnt for it.

\section*{W O R [ 743 ] W O R}
orce月ter The marquis of Worcefler is fometimes confounded Word. with John "I"ptoft, earl of Worcefler, a very acconplifh. ed literary character, who lived in the limes of Heury

V1. and Edward IV. Bcing attached to Edward, he abfonded during the fhort reftoration of Henry, and being takenconcealed in a tree in Waybridge forell in Huntingdonflire, he was brought to London, accufed of cruelty in his adminiftration of Ireland, and condemmed and beheaded at the 'lower in the year 1470. This nobleman trantlated Ciceio de Amicitia, lame parts of Cæfar's Commentaries, and was the author of feveral other works.

WORCESTERSHIRF, a county of England, hounded by Warwickfhire on the caft, by Glowcefterthire on the fuuth, by the counties of Hereford and Salop on the well, and on the north by Staffordfhire. According to ' cmpleman, it is 36 miles in length, 28 in breadth, and about 130 in circumference, within which it contains feven hundreds, and a part of two others, it market towns, of which three are boroughs, one city, nanely \(H^{\text {Torcefler, }}{ }^{1} 52\) parihes, about 540,000 acies, and I 39,518 imhabitants.

This being an inland county, well cultivated, and free from lakes, marhes, or ftagnant waters, the air is very fweet and wholefome all over it. The foil in general is very rich, producing corn, fruit, efpecially pears, of which they make a great deal of perry; hops and pafture. The hills are covered with theep, and the meadows with cattle. Hence they have wool, cloth, ftuffs, butter, and cheefe in abundance. They are allo well fupplied with fuel, either wood or coal, and falt from their brinc pits and falt fprings. Of the laft they have not only enough for themfelves, but expo:t large quantities by the Severn; which noble river, to the great convenience and emolument of the inhabitants, runs from north to fouth through the very middle of the country, enriching the foil, and yielding it plenty of fin, and an eafy expeditious conveyance of goods to and from it. The other rivers by which it is watcred are the Stour, Avon, Teme, \&c. It fends nine members to parliament, viz. two for the county, two for the city of Werceßter, two for Droitwich, two for Evelham, and one for Bewdley; and lies in the diocefe of Worcefter, and Oxford circuit.

WORD, in language, an articulate found defigred to reprefent fome idea or notion. See Grammar and Language. See alfo Logic, Part I. chap. i.

Word, or Watch-word, in military affairs, is fome peculiar word or fentence, by which the foldiers know and diftinguifh one another in the night, \&c. and by which fpies and defigning perfons are difcovered. It is ufed alfo to prevent furprifes. The word is given out in an army every night to the lieutenant or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it firft to the field-officers, and afterwards to a ferjeant of each company, who carry it to the fubalterns. In garrifons it is given after the gate is fhut to the townmajor, who gives it to the adjutants, and they to the ferjeants.

WORK, in the manege. To work a horfe, is to exercife him at pace, trot, or gallop, and ride him at the manege. 'lo work a horfe upon volts, or head and haunches in or between two heels, is to paffage him, or make him go fidewifc upon parallel lines.

To Work, in fea language, is to direct the morements of a fhip, by adapting the fails to the force and direction of the wind. See Seamansmp.

Work, Carpenters, Clock, Crown, Ficld, Fire, Fret, Grosefque, Horn, Mofaic. See the feveral articles, to. gether with Fortification and Pyrotechax.

WORK-Houfe, a place where indigent, vagrant, and idle people, are fet to work, and fupplied with food and clothing.

Work-houfes are of two kinds, or at leaft are em. ployed for two different purpofes. Some are ufed as prifons for vagrants or flurdy beggars, who are there confined and compelled to laboui for the benefit of the focity which maintains them; whilf others, fometimes called poor-houfes, are charitable afylums for fuch indigent perfons as through age or infirmity are unable to fupport themfelves by their own labour. The former kind of work-houfe, when under proper management, may be made to ferve the beft of purpofes; of the latter we are acquainted with none which entirely commands our approbation.

To make confinement in a work-houfe operate to the correction of vagrants and diforderly perfons (and if it produce not this effeet it can hardly be confidered as a beneficial inftitution), the prifoners fhould be fhut up in feparate cells, and compelled to labour for their own fubfiftence. A crew of thieves and vagabonds affociating with each other is a hell upon earth, in which every individual is hardened in his crimes by the countenance and converfation of his companions; and wretches who, when at liberty, choofe to beg or fleal rather than to carn a comfortable livelihood by honeft induftry, will fubmit to any punifhment which a humane overfeer can inflict rather than work for the benefit of others. No punifhment indeed will compel a vagrant to labour. He may affume the appearance of it, but be will make no progrefs; and the pretext of fickne!s or weaknefs is ever at hand for an excule. Hence it is that thieves and
ftrumpets

\section*{W O R [ 744 ] W O R}

Toik-
houre.
frumpets are too often difmiffed from work-houfcs and bridewells ten times more the children of the devil than when they entered them.

To remedy thefe evils, we can think of no better method than to confine eash prifoner in a cell by himfelf, and to furnifh him daily with fuch an allowance of bread and water as may preferve him from immediate death; for the only compulfion to make fuch men work ferioully is the fear of want, and the only way to reform them is to leave them to their own meditations on the confequences of their paft conduct. There are furely very few perfons, if any, whofe averfion from labour would not be conquered by the pinchings of hunger and the certain profpect of perihhing by famine; and it is to be hoped that there are not many fo totally divefted of every latent principle of virtue as not to be brought by fuch folitude to a due fenfe of their former wickednefs. Should one or two, however, be occafionally found fo very obdurate as to fuffer themfelves to perifi rather than work, their deaths would prove a falutary beacon to others, and their blood would be on their own heads; for we have the exprefs command of St Paul him. felf, that "if any will not work, neither fhould he eat."

No doubt it would be proper that the meditations of vagabonds confined in a work-houfe fhould be directed by the private admonitions of a pious and intelligent clergyman; but it is not every clergyman who is qualified to difcharge fuch a duty. If he be actuated by a zeal not according to knowledge, or if he have not with equal care fludied human nature and the word of God, his admonitions will be more likely to provoke the profane ridicule of his auditor, and harden him in his wickednefs, than to excite in his breaft fuch forrow for his fins as flall "bring forth fruits meet for repentance." To render the inftruction of thieves and vagrants of any ufe, it muft be accurately adapted to the cafe of each individual ; and however excellent it may be in itfelf, it will not be liftened to unlefs offered at feafons of uncommon ferivufness, which the inftruftor fhould therefore carefully obferve.

That fuch wholefome leverity as this would often reform the inhabitants of work-houles, appears extremely probable from the effeets of a fimilar treatment of common proflitutes mentiuned by Lord Kames in his Sketches of the Hiftory of Man: "A number of thofe wretches were in Edinburgh confined in a houfe of correction, on a daily allowance of threepence, of which part was embezzled by the fervants of the houfe. Pinching hunger did not reform their manners; for being abfolutely idle, they encouraged each other in vice, waiting impatiently for the hour of deliverance. Mr Stirling the fuperintendant, with the confent of the magiftrates, removed them to a clean houfe; and, inftead of money, appointed for each a pound of oatmeal daily, with falt, water, and fire for cooking. Relieved now from diftrefs, they longed for comfort. What would they not give for milk or ale? Work (fays he) will procure you plenty. To fome who offered to fpin, he gave flax and wheels, engaging to pay them half the price of their yarn, retaining the other half for the materials furnifhed. The finners earned about ninepence wcekly; a comfortable addition to what they had before. The reft undertook to fpin, one after another; and before the end of the firf quarter they were all of them intent upon work. It was a branch of his plan to fet free
fuch as merited that favour; and fome of them appeared to be fo thoroughly reformed as to be in no danger of a relaple."

Work-houfcs erected as charitable afylums appear to us, in every view that we can take of them, as infitutions which can ferve no good purpofe. Economy is the great motive which inclines people to this mude of providing for the poor. 'There is comparatively but a very fmall number of mankind in any country fo aged and infirm as not to be able to contribute, in fome degree, to their fubfiftence by their own labour; and in fuch houfes it is thought that proper work may le pro. vided for them, fo that the public fhall have nothing to give in charity but what the poor are abfolutely unable to procure for themfelves. It is imagined likewife, that numbers collefted at a common table, can be maintained at lefs expence than in feparate houles; and foot foldiers are given for an example, who coald not live on their pay if they did not mefs together. But the cafes are not parallel. "Soldiers having the management of their pay, can club for a bit of meat ; but as the inhabitants of a poor-houfe are maintained by the public, the fame quantity of provifions mult be allotted to each. The confequence is what might be expected: the bulk of them referve part of their victuals for purchafing ale or Spirits. It is vain to expect work from them : poor wretches void of thame will never work ferioufly, where the profit accrues to the public, not to themfelves. Hunger is the only effectual means for compelling fuch perfons to work *."

The poor, therefore, fhould be fupported in theirstames's own houfes; and to fupport them properly, the firl thing to be done is, to eftimate what each can earn by his own labour; for as far only as that falls ftort of maintenance, is there room for charity. In repairing thofe evils which fociety did not or conld not prevent, it ought to be careful not to counterabt the wife purpofes of nature, nor to do more than to give the poor a fair chance to work for themfelves. The prefent diffrefs mult be relieved, the fick and the aged provided for; but the children muft be inftrueted; and labour, not alms, cffered to thofe who have frme ability to work, however fmall that ability may be. They will be as induftrious as poflible, becaufe they work for themfelves; and a weekly fum of charity under their own management will turn to better account than in a poor-houfe under the direction of mercenaries. Not a penny of it will be laid out on fermented liquors, unlefs perhaps as a medicine in ficknefs. Nor does fuch low fair call for pity to thofe who can afford no better. Ale makes no part of the maintenance of thofe who, in many parts of Scotland, live by the fweat of their brows; and yet the perfon who Ghould banifh ale from a charity work-houfe, would be exclaimed againft as hard-hearted, and even void of humanity.

That luch a mode of fupporting the poor in their own houfes is practicable, will hardly admit of a difpute; for it has been actually put in practice in the city of Hamburgh ever fince the year 1788 . At that period fuch revenues as had till then been expended in alms by the feveral church-wardens, and thofe of which the adminiftration had been conuected with the workhoufe, were unitcd under one adminiflration with fuch fums as were collected from private benevolence. The city was divided into fixty diftricts, containing each an

\section*{W O R [ 745 ] W O R}
equal number of poor; and over thefe 18 o overfeers were appointed. Actual relicf was the firf object ; but at the very moment that this provifion was fecured, mealures were taken to prevent any man from receiving a flilling which he could have been able to earn for himfelf. By thefe methods, which our limits will not permit us to ftate, the overfeers were able to make a calculation tolerably exact of what cach pauper wanted for bare fubfiftence, in addition to the fiuits of his own labour. A flax-yarn-fpinning manufacture was eftablithed, in which the yarn is paid for, not by its weight, but by its meafure. The clean fias is fold to the poor at a low price, and a certair meafure of yarn again bought from them at 30 per cent. above the ufual price; fo that the overfeers are fure that all the yarn fpur by the poor will be brought into their office. Every pauper brings with him a book in which the quantity delivercd is carefully noted down, which furnifics the overfeers with a continual average of the flate of induftry among their poor.

As foon as this inflitution was eftablifhed, the overfeers went through their diftricts, and akked, in all fuch inanfions as could be fuppofed to harbour want, if the inhabitants flood in need of fupport? 'The quention to all fuch poor as withed for relief, and were able to Cpin, was, Whether they did earn by their work 1s. 6d. aweek? for experience had taught the inhabitants of Hamburgh, that many poor live upon that fum ; and they knew enough of their poor to fuppofe, that 1 s .6 d . avowed earning was equal to fomething more. If the anfwer was affirmative, the pauper food not in need of weekly affifance. If it was negative, work was given him, which, by being paid 30 per cent. above its value, alforded him is. 6d. a-week eafily, if he was even an indifferent hand. The far more frequent cales were partial inability by age, or weaknefs, or want of 1 kill. For poor of the latter defcription a fchool was opened, and in three months time the bulinefs was eafily learnt. During that time, the pauper got firt 2 a a-week, and every week afterwards 2 d . lefs, till in the tweifth week lie got notling at all but his earnings, and was difiniffed, with a wheel and a pound of flax gratis.

The quantity of work which difabled poor were capable of doing in a week was eafily and accurately afcertained by a week's trial in the fpinning-fchool. The refult was produced weekly before appointed members of the committee, and the fum which the poor could earn was noted down in their fmall buoks. The overfeer was directed to pay them weekly what their earnings fell hort of 1s. 6 d . in every fuch weck, when it appeared from their books that they had earned to the known extent of their abilities. From that moment applications became lefs frequent; and the committee had an infallible flandard for diftinguithing real want: for whenever the pauper, if in health (if not, he was peculiarly provided for), had not earned what he could, then he had either heen lazy, or had found more lucrative work; in either cale, he was not entitled to a relief for that week, whatever he might be for the following.

This mode of providing for the foor, which attracted the notice and obtained the culogium of the minifler and the Britilh houfe of commons has for fix years been in Hamburgh attended with the happielt confequences. In the ftreets of that city a beggar is rarcly

Vol. XX. Part II.
to be feen, whilt thofe who fland in need of the charitable contributions of the rich, are much more confurtably, as well as at much lefs expence, maintained at home, with their children about them, than they could be in work-houfes, under the management of mercenary overfeers. For a fuller account of this judicious intlitution, we muft refer the readers to Vaght's Account of the Management of the Puor in Hamburgh, fince the year 1788 , in a Letter to fome Friends of the Poor in Great Britain.

Worms for bait. See Fishing.
Worms, an ancient, large, and famous city of Germany, in the palatinate of the Rhine, with a bimop's fee, whofe bilhop is a fovereign and prince of the empire. It is a free and imperial city, and the inhabitants are Protellants. In the war of 1689 it was taken by the French, who almoft reduced it to athes.-The biflop afterwards built a new palace in it ; and it is famous for a diet held here in 152 I , at which Luther affifted in perfon. 'The Proteftants have lately built a handfome church, where Luther is reprefented as appearing at the diet. It is noted for the excellent wine that grows in the neighbourhood, which they call our lady's milk. In the campaign of 1743 , King Geo. II. took up his quarters in this city, and lodged at the bithop's palace after the battle of Dettingen. It is feated on the weltern bank of the Rhine, 14 miles north-weft of Heidelberg, 20 fouth-eat of Mentz, and 32 fouthweft of Vranckfort. E. L.ong. 8. 29. N. Lat. 49. \(3^{2}\).

WORMING of nogs. All dogs have certain flrings under their tongues, by moft called a worm; this muft be taken out when they are about two months old, with the help of a harp knife to flit it, and a thoemaker's awl to raife it tip; you mult be careful to take all out, or elfe your pains is to little purpofe; for till then he will be bardly ever fat and right, in regard the worm or ftring will grow foul and troublefore, and hinder his reft and eating. This cruel operation is generally recommended as a preventive of madnefs in dugs, or at leaft as dilabling them, if mad, from biting in that condition.

In this operation, of which the rulgar account is gi5 B

ทen.

Worl-
lante \| Worming.

Worming ven above, which we have junly denominated a cruel one, it is not a flring that is removed, but the duct by which the faliva is conveyed from the gland in which it is fecreted to the mouth for the purpofe of mixing with the food and promoting its deglutition and digeftion. Now this operation by no means prevents the animal from biting, nor can it, in our opinion, obftruet the flow of the faliva by which the dreadful difeafe hydrophobia is communicated.

WORMIUS, Olaus, a learned Danifh phyfician, born in 1588 at Arhufen in Jutland. After beginning his fludies at home, he fludied at feveral foreign univerfities, and travelled to various parts of Europe for improvement. He returned to his native country in 1613 , and was made profeffor of the belles lettres in the univerfity of Copenhagen. In 1615 , he was tranflated to the chair of the Greek profeflor; and in 1624 to the profefforfhip of phyfic, which he held to his death. Thele occupations did not hinder him from practifing in his profeffion, and from being the fafhionable phyfician: the king and court of Denmark always employed him ; and Chrinian IV. as a recompenfe for his fervices, conferred on him a canonry of Lunden. He publifhed fome pieces on fubjects relating to his profeffion, feveral works in defence of Ariftotle's philofophy, and feveral concerning the antiquities of Denmark and Norway ; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died in 1654 .

WORMWOOD. See Artemisla, Botany In. dex.

WORSHIP of God (cullus Dei), amounts to the fame with what we otherwife call religion. This worfhip confilts in paying a due refpect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal refpeet, \&c. is to be thown and teflified by external acts; as prayers, facrifices, thankrgivings, \&c.

The Quietifts, and fome other myllic divines, fet afide not only all ufe of external worfhip, but even the confideration of rewards and punifhments. Yet even the heathens had a notion that God did not require us to ferve him for nought: "Dii quamobrem colendi fint ( Cays Cicero), non intelligo, nullo nec accepto ab illis nec fperato bono."

The fchool-divines divide worhip into divers kinds, viz. latria, that rendered to God; and idololatria, that rendered to idols or images. 'lo which the Romanifts add, dulia, that rendered to faints; and hyperdulia, that to the Virgin. Some theological writers have obferved, that the Greek word, \(\pi\) gooxuvs \(\omega\), to wor/hip, is not defcriptive only of the honour which is appropriated to God, but is indifferently ufed to fignify the honour and refpect swhich are paid to fuperiors of all kinds in heaven or on earth. Accordingly, they have diftinguilhed between civil and religious worhip.

That it is the duty of man to worfhip his Maker, has beenf fufliciently proved under other articles (fee Praybre; and Theology, \(\mathrm{N}^{\circ}\) 40-45.). It is not indeed eafily to be conceived how any one who has tolerably juft notions of the attributes and providence of God, can poffibly neglect the duty of private workip; and though we have admitted in the laft of the two articles referred to, that public worlhip does not feem to be enjoined in that fyltem which is called the religion of na-
ture, yet it is moft exprefsly commanded by the religion Wornhip of Christ, and will be regularly performed by every one who retlects on its great utility.

As the illiterate vulgar cannot form to themfelves correct notions of the divine providence and attributes, it is obvious, that without the inflitution of public worfhip, they would never think of worfhipping God at all, unlefs perhaps occafionally, when under the preflure of fome fevere calamity; but occafional worthip, the offSpring of compulion, could have little of the refigned firit of true devotion. Ignorant, however, as the lowelt of the vulgar are, and neceffarily muft be, it cannot be denied, that in moft Chriftian countries, perhaps in all, they are more accurately acquainted with the firn principles of religion, and the laws of morality, than even the leaders of barbarous nations. This fuperiority is doubtlefs owing in fome meafure to their accefs to the Sacred Scriptures, but much more, we are perfuaded, to the inftruction which they receive in the affemblies which they frequent for public workhip. If this be admitted, public worfhip nay be eafily proved to be the duty of every individual of the community : For were thofe, who may be fuppofed to fland in no need either of the contagion of fociety to kindle their own devotion, or of the preaching of a clergyman to inflruct them in the doctrines and precepts of the gofpel, to "forfake, on thefe accounts, the affembling themfelves together, as the manner of fome is," religious afiemblies and public worfhip would very quickly fall into univerfal difufe. Man is an animal prone to imitation ; and every order in fociety is ambitious of treading in the footfeps of the order immediately above it. Were the wife and the good, therefore, permitted to abfent themfelves from the affemblies inftituted for the public worthip of the Creator and Redeemer of the world, others would quickly follow their example; impelled to it not only by this univerfal propenfity, but by the additional motive of wifhing to appear both to the world and to themfelves as wife and as good as their privileged neighbours. The confequence is obvious: one man would fay from church with the ferious intention perhaps of employing the Lord's day in private devotion and religious fludy; another, following his example, would abfent himfelf upon the fame pretence, but would in reality wafte the day in dozing indolence or in fecret fenfuality. For thefe and other reafons which might be eafily affigned, no fincere Chriftian will think himfelf at liberty to difpute a practice enjoined by the infpired preachers of his religion, coeval with the innitution, and retained by every fect into which it has fince been unhappily divided.

As Chriftian worhip confifts of prayers and praifes, it has been a matter of fome debate whether it is moft properly performed by preconcerted forms or liturgies, or by extemporaneouis addreffes to the Almighty. Both thefe modes have their advantages and diladvantages; and by the facred writers neither of them is prefribed in oppofition to the other.

The advantages of a liturgy are, that it prevents abfurd, extravagant, or impious addreffes to God, which the folly or enthufiafm of individuals muft always be in danger of producing ; it gives the congregation an opportunity of joining in the prayers whicl2 are put up for them, which they cannot poffibly do in a fenies of extemporaneous petitions, fince before they can affent to

\section*{W O R [ 747 ] W O T}

Sorihip, any one of thefe and make it their own, their attention Wort. is neceffarily called away to that which fucceeds it; and it relieves the clergyman from the labour of compofition, which feems incompatible with that fervour which conllitutes the firit of devotion.

The difadvantages of a fixed liturgy, which are the recommendations of extemporary prayer, are principally two. The forms compoled in one age mult, by the unavoidable change of language, circumftances, and opinions, become in fome degree unfit for another; and the perpetual repetition of the fame form of words is very apt to produce inattentive laflitude in the congregation. Would the clergy of the church of England take that liberty which is allowed them in the biddiug prayer before fermon, perhaps the fervice of that church would unite in itfelf all the advantages both of liturgic and extemporary worthip. We have only to add on this fubjeet, that public prayers, whether precompofed or not, ought to be compendious; that they ought to exprefs juit conceptions of the Divine attributes; recite fuch wants as the congregation are likely to feel, and no other; that they ought to contain as few controverted propofitions as polible; and that, if it cam be done without offence, the pompous flyle of the Mate fhould be laid afide in our prayers for the king and all that are in authority; becaufe in every aft which carries the mind to God, human greatnefs mult be annihilated.

WOR'T, the infufion of malt, of which beer is made. See Brewing. The ufes of this infufion in common affairs are well known. By Dr M'Bride it has lately been found to have a frong antifeptic virtue, and to be ufeful in preventing the fcurvy and other difeafes to which failors are liable; this was confirmed by Captain Cook in his voyages. See Means of Preferving the Hcalth of SEAMEN.

It is of great importance to the manufacturer to be able to afcertain with facility and precifion the real ftength of worts, or the quantity of faccharine matter contained in the infufion. This is accomplifhed by determining the fpecific gravity by means of inftruments, which, from the purpofe to which they are applied, have obtained the name of faccharomeicrs. But as thefe infruments, from the very nature of the material of which they are conftructed, are liable to confiderable change, the refults which they afford cannot always be depended on. With the view of obviating thefe inconveniencies, the patent areometrical beads have been invented by Mrs I.ovi of Edinburgh. We have already noticed thefe beads, on account of their accuracy, fimplicity, and facility of application for afcertaining the Specific gravity, or the real firength and value, of firituous liquors. See vol. six. p. 599. ; and we now recommend them with greater confidence, from having had opportunities of knowing that they are capable of a more extended application, as in the manufacture of acids, and falts of different kinds; to afcertain the ftrength of acids, or that of faline folutions in bleaching ; to deter. mine the flrength of liquids employed in the different procefles of calico printing and dyeing, and not only for the purpole of examining the ftragth of the acids employed, but alfo particularly to afcertain the denfity or fpecific gravity of the colouring matters which are ufed in thefe arts, fo that the fame degree of thade required may be always obtained. It has been fingefted, that thefe beads might be conveniently employed in determining
the ftrength of mineral waters, which, it is well known, vary confiderably at different feafons of the year.
\(\Lambda_{s}\) the patent beads are conftrueted on the fame principle from 800, the fpecific gravity of alcohol, to 2000, which is double the Specific gravity of water; and as they are divided into different feries, each of which includes a range of fpecific gravities applicable to the particular fluids, the denfily or ftrength of which is required, we have no hefitation in afferting that they will be found extremely convenient and ufeful to all manu. facturers and dealers, who wifl to afcertain with accuracy the real ftrength and value of liquids.

It has been objected to the ufe of thefe beads, that they require a longer time than other inftruments in ufing them. The fame objection has been made to the introduction of other new influments, the application of which frequent ufe has afterwards rendered familiar and ealy. We have had opportunities of knowing that this objection is completely obviated, by thofe who have been accuftomed to ule the beads. They find that they can determine the fpecific gravity of a liquid by means of the beads with the fame facility, and in as fhort a time, as with any other inflrument.

WOT'TON, Sir Henry, an eminent writer, was the fon of Thomas Wotton, Efq. and was born in 1568. He ftudied for fome time at New-college, Oxfurd, whence he removed to Queen's-college, where he made a great progrefs in logic and philofophy ; wrote a tragedy for the ufe of that college, called Tancredo; and afterwards reccived the degree of mafter of arts. After this, leaving the univerfity, be travelled into France, Germany, and Italy; and having fent about nine years abroad, he returned to England, and became fecretary to Robert earl of Effex, with whom he continued till that earl was apprehended for high-treafon. He then retired to Florence, where he became known to the the grand duke of Tufcany, who fent him'privately with letters to James VI. king of Scotland, under the name of OATavio Baldi, to inform that king of a defign againt his life. Some months after he went back to Florence; but King James coming to the poffeflion of the crown of England, Mr Wotton returned home, was knighted by his majefty, and fent ambaffador to the republic of Venice; and afterwards was employed in many other embaflies to that and other courts; but the only reward he obtained for thefe fervices was his having the provofthip of Eton conferred upon him about the year 1623, which he kept till his death, which happened in 1639. After his deceaie fome of his manufcripts and printed tracts were publifued together in a volume, intitled, Reliquiae Wottoniante.

Wotton, Dr William, a learned divine and writer, was the fon of Mr Henry Wotton, B. D. rector of Wrentham, in Suffolk, where he was born in 1666. He was educated by his father, a gentleman well filled in the learned languages; under whom he made fuch amazing proficiency, that at five years of age it is faid he could render feveral chapters in the gofpels out of Latin and Greek, and many pfalms in Hebrew, into his mother tongue. When he was very young, he remembered the whole of almof every difcourfe he bad heard, and often furprifed a preacher by repeating his fermon to him. He was admitted into Catharine-hall in Cainbridge fome months before he was ten years old; when the progrefs he made in learning in that univerfity en-

Wation, Wounds.
gaged Dr Duport, then mafter of Magdalen college, and dean of Peterborough, to write an elegant copy of Latin verfes in his praife. In 1679 he took the degree of bachelor of arts when he was but twelve years and five months old; and the winter following he was invited to London by Dr Gilbert Burnet, then preacher at the Rolls, who introduced him to moft of the learned men in that city, and particularly to Dr William Lloyd, bifhop of St Afaph; to whom he rccommended himfelf by repeating to him one of his fermons, as Dr Burnet had engaged he fhould. In 169 I he commenced bachelor of divinity. The fame year Biflop Lloyd gave him the finecure of Llandrillo, in Denbighaire. He was afterwards made chaplain to the earl of Nottingham, then fecretary of fate, who prefented him to the rektory of Middleton Keynes, in Bucks, and to whom he dedicated his Reflections upon Ancient and Modern Learning. In 1705 , Bithop Burnet gave him a prebend in the church of Salifbury; and in 1707, Archbifhop Tenifon prefented him with the degree of doctor of divinity: but in 1714 , the difficulties he laboured under with refpect to his private fortune, obliged him to retire into South Wales, where he was treated witly great kindnefs and humanity by the gentlemen of that country; and wrote there the "Memoirs of the Cathedral Churches of St David's and Landaff," and his "Mifcellaneous Difcourfes relating to the Traditions and Ulages of the Scribes and Pharifees;" which were afterwards printed. He died in 1726 . This great man was remarkable for his humanity and friendlinefs of temper ; the narrownefs of a party fpirit never broke in upon any of his friend/hips; and his time and abilities were at the fervice of any perfon who was making advances in real learning. He wrote, befides the above works, 1. A Hiftory of Rome. 2. A Defence of his Reflections upon Ancient and Mudern Learning. 3. A Difcourfe concerning the Languages of Babel. 4. Advice to a young Student, with a Method of Study for the firf four Years; and other learned pieces.

WOUNDS, in Surgery, have been divided into fimple, contufed or lacerated, and gun-got.

Of Simple lWounds. - The firft thing to be confidered in the infpection of a wound is, whether it be likely to prove mortal or not. This knowledge can only be had from anatomy, by which the furgeon will be able to de. termine what parts are injured; and, from the offices which thefe parts are calculated to perform, whether the human frame can fubfift under fuch injuries. It is not, however, eafy for the moft expert anatomilt always to prognofticate the event with certainty; but this rule he ought always to lay down to himfelf, to draw the mof favourable prognofis the cafe will bear, or çen more than the rules of his art will allow. This is particularly incumbent on him in fea-engagements, where the fentence of death is exccuted as foon as pronounced, and the miferable patient is thrown alive into the fea, upon the furgeon's declaring lis wound to be mortal. 'There are, befides, many inftances on record, where wounds have healed, which the mof ikilful furgeons have deemed mortal. The following wounds may be scckoned mortal.
1. Thofe which penetrate the cavities of the heart, and all thofe wounds of the vifcera where the large blood-veliels are opened; becaufe their fituation will

not admit of proper applications to reftrain the flux of Wounds. blood.
2. Thofe which entirely cut off the paffage of the ner ous influence through the body. Such aie wounds of the brain, cerebellum, medulla oblongata, and fpiral marrow. Wounds likewife of the fmall blood-veffels within the brain are attended with great danger, from the effufed fluids prefling upon the brain. Nor is there lefs danger where the nerves which tend to the heart are wounded, or eutirely divided; for, atter this, it is impollible for the heart to continue its motion.
3. All wounds which entirely deprive the animal of the faculty of breathing:
4. Thole wounds which interrupt the courfe of the chyle to the heart; fuch are wounds of the receptacle of the chyle, thoracic duct, and larger lacteals, \&c.
5. There are other wounds which prove fatal if neglected and left to nature: fuch are wounds of the larger external blood-veffels, which might be remedied by ligature. Wounds of fuch parts generally prove fatal ; and though a few inftances may have occurred where people have recovered after them, yet they are always to be confidered as extremely dangerous. Portions of the brain have been deffroycd, and wounds have been made into it, and the patients have lived. It is poffible, too, that the thoracic duct might be wounded and the patient live; Mr A. Cooper having fhown, in. a very ingenious paper in the Medical Records and Refearches, that it may become obftructed, and the chyle conveyed into the fyftem by anaftomofing lymphatics.

In examining wounds, the next confideration is, whe- Symptoms ther the parts injured are fuch as may be fuppofed 10 of wounds induce dangerous fymptoms, either immediately or at in different fome period during the courfe of the cure. In order to body. proceed with any degree of certainty, it is neceffary to be well acquainted with thofe fymptoms which attend injuries of the different parts of the body. If the 0 in and part of the cellular fubftance are only divided, the firft effects are an effufion of blood; the lips of the wound retract, become tumefied, red and inflamed, leaving a gap of confiderable widenefs according to the length and deepnefs of the wound. If a very confider- of wounds able portion of Nkin and cellular fubfance is divided, a of the fkin flight fever feizes the patient; the effufion of blood in and celluthe mean time fops, and the wound is partly filled up fance. with a cake of coagulated blood. Below this cake, the fmall veffels pour forth a clear liquor, which in a flort time is converted into pus (fee the articles Pus and Mucus). Below this pus granulations of new flefh arife, the cake of coagulated blood loofens, a new ikin covers the place where the wound was, and the whole is healed up; and there only remains a mark, called a cicatrix or far, fhowing where the injury had been received.

All wounds are accompanied with a confiderable de- of the muf. gree of pain, efpecially when the inflammation comescles. on, though the divifion reaches no farther than the fkin and cellular fubftance. If the mufcular fibres are divided, the pain is much greater, becaufe the found part of the mufcle is fretched by the contraction of the divided part and the action of the antagonit mufcle, which it is now lefs fitted to bear. The wound alfo gaps much more than where the cellular fubflance is

\section*{W O U \(\quad 1749] \quad W \quad O \quad U\)}

Wounds. alone divided, infomuch that, if left to itfelf, the ikin will cover the mufcular fiores, without any intervention of cellular fubfance ; and not only a very unfightly cicatrix remains, but the ufe of the mufcle is in lome meafure loft- If the mufcle happens to be totally divided, its fibres retract to a very confiderable diftance; and unIefs proper methods be taken to bring them into contact, the ufe of it is ever afterwards loft.

If by a wound any confiderable artery happens to be divided, the blood llows out with great velocity, and by flarts; the patient foon becomes faint with lofs of blood; nor does the hæmorrhagy flop until he faints away altogether; and if as much vis vitce ftill remains as is fufficient to renew the operations of life, he recovers after forne time, and the wound heals up as ufual. The part of the artery which is below the wound in the mean time becomes ufelefs, fo that all the inferior part of the limb would be deprived of blood, were it not that the fmall branches fent off from the artery above the wounded place become enlurged, and capable of carrying on the circulation. Nature alfo, after a wonderful manner, often produces new velfels from the fuperior extremity of the divided artery, by which the circulation is carried on as formerly. The confequences of fuch a profufe hæmorrhagy may be, however, very dangerous to the patient, by inducing extreme debility, or an univerfal droply. This great hæmorrhagy happens efpecially where the artery is partially divided; bccaufe then the veffel cannot contract in fuch a manner as to clofe the orifice: however, if the wound is but fmall, the blood gets into the cellular fubftance, fwelling up the member to an extreme degree, forming what is called a diffufed aneurifm. Thus the hwemorrhagy foon ftops externally, but great mifchief is apt to flow from the confinement of the extravafated blood, from bringing on exterior fuppuration among the mufcles and bones; and thus not only the ufe of the limb is entirely loft, but the patient is brought into great danger of his life.
Of the ligaments, nerves, and Itendons.

Wounds of the ligaments, nerves, and tendons, are likewife attended with bad confequences. When a nerve is entirely divided, the pain is but trifing, thongh the confequences are often dangerous. If the nerve is large, all the parts to which it is diffributed below the wound immediately lofe the power of motion and fenfation. This, however, takes place only when all or the greateit part of the nerves belonging to a particular part are divided. If the fpinal marrow, for inftance, be divided near the head, the parts below foon lofe their fenfation irrecoverably; or if the bundle of nerves paffing out of the axilla be divided or tied, fenfation in the greatelt part of the arm below will be loft. But though a nerve fhould be divided, and a temporary palfy be produced, it may reunite, and perform its forner functions. If a nerve be wounded only, inftead of being divided, the worft fymptoms frequently enfue.
Wounds which penetrate the cavities of the thoras are always exceedingly dangerous, becaufe there is fcarce a polfibility of all the vifcera efcaping unlurt. A wound is known to have penetrated the cavity of the thorax principally by the difcharge of air from it at each infpiration, by an extreme difficulty of breathing, and by coughing up blood. Such wounds, however, are not always mortal ; the lungs have frequently been wounded, and yet the patient has recorered.-Wirounds
of the diaphragm are almoft always mortal, either by
Wiounds. inducing fatal convulfions immediately, or by the afcent of the Itomach, which the preffure of the abdominal mufcles forces up through the wound into the cavity of the thorax; of this Van Swieten gives liveral inllances. -Even though the wound do not penetrate into the cavity of the thorax, the very wort fymptoms may follow. For if the wound defcends deeply among the external mufcles, and its orifice lies higher, the extravafated blood will be therein colleeted, flagnate, and form various finules; which after having croded the pleura, may at length pafs into the cavity of the thorax. The matter having once found a vent into this cavity, will be continually augmenting from the difcharge of the finuous ulcer, and the lungs will at laft fuffer by the furrounding matter. If, in cafes of wounds in the thorax, the ribs or fternum happen to become carious, the cure will be extremely tedious and difficult. Galen relates the cafe of a lad who received a blow upon his fternum in the freld of exercife: it was firf negrocted, and afterwards badly healed; but, four month; afteruards, matter appeared at the place which had reccived the blow. A phyfician made an incifon into the part, and it was foon after cicatrized : but in a thort time a new collection made its appearance, and upon a fecond incifion the wound refufed to heal. Galen found the Nernum carious; and having cut off the difeafed part, the pericardium itfelf was obferved to be corroded, fo that the heart could be feen quite naked; notwithfandin: which, the wound was cured in no very long time.

There is fometimes difficulty in deternining whether the wound has really penetrated into the thoras or into the abdomen; for the former defeends much farther towards the fides than at the middle. But as the lungs are almont always wounded when the cavity of the tho rax is penctrated, the fymptoms arifing from thence can fcarcely be miltaken.- Another fymptom which frequently, though not always, attends wounds of the thorax, is an emphyfema. This is occafioned by the air efcaping from the wounded lungs, and infinuating itfelf into the cellular fubflance; which being pervious to it over the whole body, the tumor pafies from one part to another, till at laft every part is inflated to a furprifing degree. An intance is given in the Memoirs of the Royal Academy, of a tumour of this kind, which on the thorax was eleven inches thick, on the abdomen nine, on the neck fix, and on the reft of the body four; the eyes were in a great meafure thruft out of their orbits by the inflation of the cellular fubflance; and the patient died the fifth day. This was occafioned by a flab with a frord.

W'ounds of the abdomen are not lefs dangerous than of the abthofe of the thorax, on account of the importance of domen and the vifcera which it contains. When the wound doesits vilicers. not penetrate the cavity, there is iome danger of a hernia being formed by the protrufion of the peritonæum through the weakened integuments, and the danger is greater the larger the wound is. Thofe wounds which run obliquely betwixt the interfices of the mufcles often produce finoous ulcers of a bad kind. For as there is a large quantity of fat interpofed everywhere betwist the mufcles of the abdomen, if a wound happens to run between them, the matter there collected, not meeting with free egiefs through the mouth of the wound, often makes its why in a furprifing manner through the cellow

Wounds. lar fubifance, and forms deep finuofities batween the mufcies; in which cafe the cure is always difficult, and fometimes impoffible.

If a large wound penetrate the cavity of the abdomen, fome of the vifcera will certainly be protruded through it ; or if the wound is but fmall, and clofed up with tat fo that none of the inteflines can be protruded, we may know that the cavity of the abdomen is pierced, and probably fome of the vifcera wounded, by the acute pain and fever, palenefs, anxiety, faintings, hiccough, cold fweats, and weakened pulfe, all of which accompany injuries of the internal parts. The milchiefs which attend wounds of this kind proceed not only from the injury done to the vilcera themfelves, but from the extravafation of bload and the difcharge of the contents of the inteftines into the cavity of the abdomen; which, being of a very putrefcent nature, foon bring on the moft violent diforders. Hence wounds of the abdominal vilcera are very often mortal. This, however, is not always the cafe, for the fmall inteftines have been totally divided, and yet the patient has recovered. Wounds both of the fmall and large inteflines have healed fpontaneoufly, even when they were of fuch mag. nitude that the contents of the inteftine were frecly difcharged through the wound into the abdomen, and after part of the inteftine itfelf has been protruded through the wound of the integuments.

When the mefentery is injured, the danger is extreme, on account of its numerous veffels and nerves. Wounds of the liver, 〔pleen, and pancreas. are alfo exceedingly dangerous, although there are fome inflances of the fpleen being cut out of living animals without any confiderable injury.

From the preceding account of the fymptoms attending wounds in the different parts of the body, the furgeon may be enabled to judge in fome meafure of the event; though it muft always be remembered, that wounds, even thofe which feemed at firf to be of the flighteft nature, have, contrary to all expectation, proved mortal, chiefly by inducing convulifions, or a locked jaw; fo that no certain prognoftic can be drawn on fight of recent wounds. We fhall now, however, proceed to confider their treatment.
will almof always heal by adhefion. When a wound Wounc: does not heal by this procefs, there are three flages to be obferved in its cure ; the firlt, called fuppuration, whirh takes place when the ends of the wounded veffels contract themfelves, and pour out the liquor which is converted into pus. As foon as this appears, the fecond, or granulating fage, in which the flefl begins to grow up, takes place; and as this proceeds, the edges of the wound acquire a fine bluith or pearl colour, which is that of the new f-in beginning to cover the wound as far as the granulations have filled it up. This procels continues, and the k in advances from all fides towards the centre, which is called the cicatrizing of the wound. For the promoting of each of thefe proceffes, feveral ointments were formerly much in vogue. But it is now found, that no ointment whatever is capable of promoting them ; and that it is only neceffary to keep the wound clean, and to prevent the air from having accefs to it. This, indeed, nature takes care to do, by covering the wound with a cake of coagulated blood; but if a wound of any confiderable magnitude thould be left entirely to nature, the pus would form Lelow the cruft of coagulated-blood in fuch quantity, that it would molt probably corrupt, and the wound degenerate into a corroding ulcer. It is neceffary, therefore, to clearfe the wound frequently; for this purpofe it will be pro per to apply a little ointment fpread on foft fcraped lint. And, in a healthy body, the wound will heal without further trouble. As to the ointment employed, it is almoll indifferent what it be, provided it has no acrid or flimulating ingredient in its compofition; hogs lard or the fimple cintment of the Pharmacopeia will anfwer perfectly.

But though, in general, wounds thus eafily admit of a cure, there are feveral circumftances which require a different treatment, even in fimple divifions of the flefly parts, when neither the membranous nor tendinous parts are injured. Theee are, 1. Where the wound is large, and gapes very much, fo that, if allowed to heal in the natural way, the patient might be greatly disfigured by the fcar. It is proper to bring the lips of the wound near to each other, and to join them either by adhefive plafter or by future, according as the wound is luperficial, or deep. 2. When foreign bodies are lodged in the wound, as when a cut is given by glafs, \&c. it is neceffary to extract them, before the wound is drefled: for it will never heal until they are dilcharged. When thefe bodies are fituated in fuch a manner as not to be capable of being extracted without lacerating the adjacent parts, which would occafion violent pain and other bad fymptoms, it is neceffary to enlarge the wound, fo that thefe offending bodies may be eafily removed. This treatment, however, is chiefly neceflary in gunthot wounds, of which we flall afterwards fpeak. 3. When the wound is made in fuch a manner that it runs for fome length below the Nin, and the bottom is-much lower than the orifice, the matter collected from all parts of the wound will be ladged in the bottom of it, where, corrupting by the heat, it will degenerate into a fifulous ulcer. To prevent this, we
mult
(A) See an account of the method of fucking wounds, in Mr John Bell's Difcourfis on Wounds, Part i. difcourfe v. p. 215 .

\section*{W O U}
muft ufe comprefles, applied fo that the bottom of the wound may fuffer a more confiderable preffure than the upper part of it. Ihus the matter formed at the bottom will be gradually forced upwards, and that formed at the upper part will be incapable of defcending by its weight; the divided parts, in the mcan time, eafily uniting when brought clofe together. Indeed, the power which nature has of uniting different parts of the human body is very furprifing; for, according to authors of eredit, even if a piece of ilefh be totally cut out, and applied in a fhort time afterwards to the place from whence it was cut, it will unite. That a part cut out of a living body does not entirely lofe its vital power for fome time, is evident from the modern praclice of tranfplanting teeth; and from an experiment of Mr John Hunter's, where be put the teflicle of a cock into the belly of a living hen, and the teflicle adhered to the liver, and became connected to it by means of blood-veffels *. We have therefore the greatef reafon to hope, that the divided parts of the human hody, when elofely applied to each other, will cohere without leaving any finus or cavity between them. However, if this method fhould fail, and matter be collected in the depending part of the wound, it will be neceffary to make an opening in that part in order to let it out; after which the wound may be cured in the common way. 4. During the courfe of the cure, it fometimes happens that the wound, inftead of filling up with granulations of a florid colour, fhoots up into a glaffy. like fubttance which rifes above the level of the furrounding Kin, while, at the fame time, inftead of laudable pus, a thin ill-coloured and fetid ichor is difcharged. In this cafe the lips of the wound lofe their beautiful pearl colour, and become callous and white, nor does the cicatrizing of the wound at all advance. When this happens in a healthy patient, it generally proceeds from fome improper management, efpecially the making ufe of too many emollient and relaxing medicines, an immoderate ufe of balfams and ointrients. Frequently nothing more is requifite for taking down this fungus than drefling with dry lint; at other times deficcative powders, fuch as calamine, tutty, calcined alum, \&c. will be neceflary; and fometimes red precipitate mercury muft be ufed. This laft, however, is apt to give great pain, if frinkled in its dry fate upon the wound; it is therefore molt proper to grind it with fome yellow bafilicon ointment, which makes a much more gentle, though at the fame time an efficacious efcharotic. Touching the overgrown parts with blue vitriol is alfo found very effectual.

Hitherto we have confidered the wounded patient as otherwife in a Itate of perfect health; but it mult be obferved, that a large wound is capable of difordering the fytem to a great degree. . If the patient is frong and vigorous, and the pain and inflammation of the wound great, confiderable degree of fever may arife, which it will be necellary to check by bleeding, low diet, and other parts of the antiphlogiftic regimen, at the fame time the inflamed lips of the wound and parts adjacent are to be treated with emollient fomentations or cataplafms till the pain and fwelling abate. On the other hand, it may happen, when the patient is of a weak and lax habit, that the vis vitce may not be fufticient to excite fuch an inflammation in the wound as is abfolutely necellary for its cure. In this cafe, the edges of the
wound look pale and foft; the wound itfelf ichorous Wounds. and bloody, without any figns of granulations; or if \(\underbrace{\text { - }}\) any granulations ftoot up, they are of the fungous glafly kind above mentioned. Io fuch wounds all external applications are vain; it is neceffary to ftrengthen the patient by proper internal remedies, among which the bark has a principal place, until the wound begins to alter its appearance: In fuch perfons, too, there is fome danger of a hectic fever by the abfurption of matter; and this will take place during the courfe of the cure, even when the appearances have been at firft as favourable as could he wifbed. 'This happens generally when the wound is large, and a great quantity of matter formed : lor by this dilcharge the patient is weakened; fo that the pus is no fooner formed, than it is reconveyed into the body by the abforbent veflels, and immediately affects the patient with feverifh heat. When this takes place, the beft remedy is to exhibit the bark copioully, at the fame time to fupport the patient by proper cordials and nourifhing diet. Indeed, in general, it will be found, that, in the cafe of wounds of any confiderable magnitude, a more full and nourif. ing regimen is required than the patient, even in health, has been accuftomed to; for the difcharge of pus alone, where the quantity is confiderable, proves very debilitating. And it is conftantly found, that the cure of fuch fores goes on much more eaflly when the patient is kopt in his ufual habit of body, than when his fy ftem is much emaciated by a very low allowance; and, foz the fame reafon, purgatives, taken more frcely than what is neceffary tokeep the bowels open, and whatever elfe tends to weaken the conltitution, are improper in the cure of wounds.

Hæmorrhagies very frequently happen in wounds, of hxmore either from a divifion of a large artery, or of a number rhagies of fmall ones. In this cafe, the firf ftep to be taken by from the furgeon is to effect a temporary foppage of the wounds. blood by means of compreflion, and he is then to tie up all the larger veffels according to the methods ufually directed.

When the principal arteries of a wound have been tied, and a little blood continues to be difeharged, which appears to come from fundry fmall veftels only, an experienced furgeon is induced to think, that the compreffion of the bandages will in all probability effect a total Atoppage of the hæmorrlagy. In a general oozing from the whole furface of a fore, and when no particular veffel can be diftinguithed, there is a neceffity for trufing to the bandage or compreffion; but whenever an artery can be difcovered, of whatever fize it may be, it ought to be fecured by a ligature. But it frequently happens, that confiderable quantiries of blood are difcharged, not from any particular veflel, but from all the fmall arteries over the furface of the wound ; and in wounds of great extent, particularly after the extirpation of eancerous breafts, and in other operations where extenfive fores are left, this feccies of hemorihagy often proves very troublefome by being exceedingly difficult to fupprefs.

In conftitutions perfectly healthy, on the oecurrence of wounds even of the mofl extenfive nature, as foon as the larger arteries are fecured, all the fmall veffels whiels have been divided are diminifhed, not only in their dia. meters, but alfo in their length; in confequence of which, they recede confuderably within the furface of

\section*{iv O U [ 752 ] W O}

Wivunds. the furrounding parts. This caufe of itfelf would probably, in the greatett number of inftances, prove fuf. ficient for reftraining all lofs of blood from the fmaller arterics. Another very powerful agent however is provided by nature for producing the fame effect. From the eatremities of the divided veffels which at firt difcharged red blood, there now, in their contracted Qate, oozes sut a more thin, though vifcid fluid, contaning a great proportion of the coagulable parts of the blood; and this being equally diftributed over the furface of the wound, by its agglutinating powers has a very confiderable infuence in reftraining all fuch hamorthagies.

When a tedious oozing occurs in a patient young and vigorous, and where the tone of the mufcular fibres is evidently great, the molt effectual means of putting a ftop to the dilcharge is to relas the vafcular fyftem, cither by opening a vein in fome other part, or, what gives ftill more immediate relief, by untying the ligature on one of the principal arteries of the part, fo as to allow it to bleed frecly: thofe violent fpafriodic twitchings too, fo frequent after operations on any of the extremities, when they do not depend on a nerve being included in the ligature with the artery, are in this manuer more effectually relicved than by any other means.

By the fame means the patient, from being in a febrile heat and much confufed, foon becomes very tranquil : the violent pulation of the heart and larger arteries abates, and the blood not being propelled with fuch impetucfity into the fmaller veffels of the part, they are left at more liberty to retract.

The patient ought to be kept exceedingly cool; wine and other cordials hould be rigidly avoided; cold water, acidulated either with the mineral or vegetable acids, ought to be the only drink; motion of every kind, particularly of the part affected, thould be guarded againlt; and the lip of the wound being drawn together by adhefive platter, and gently covered with loft charpie, it ought to be tied up with a bandage fo applied as to produce a moderate degree of preffure on the extremities of the divided parts.

As foon as a fufficient quantity of blood has been difcharged, the wound dreffed, and the paticnt laid to relt, a dofe of opium proportioned to the violence of the fymptoms ought to be immediately exhibited. It ought to be remarked, however, that in all fuch circumftances, much larger dofes of this medicine are neceffary than in ordinary cafes requiring the ufe of opiates. Small dofes, inftead of anfwering any good purpofe, feem frequently rather to aggravate the varicus fymptoms; fo that whenever they are had recourfe to in fuch cafes, they ought always to be given in quantities fafficient for the intended effect.

But hæmorrhagies of this nature happen much more frequently in relax.cd enfeebled habits, where the folids have loft part of their natural firmnefs, and the fluids have acquired a morbid tenuity. In this cafe a moderate ufe of generous wine ouglit to be immediately prefribed; for nothing tends fo much, in fuch circumftances, to reftrain hæmorrhagies, as a well direded ule of proper cordials. By tending to invigorate and brace the folids, they enable the arterial fyftem to give a due refiftance to the contained fluids; and lave alfo a consederable influence in reforing to the fluids that vifcidi-
ty of texture, of which in all fuch inftances we fappofe Wounds. them to be deprived.

A nouribhing diet alfo becomes proper; the patient ought to be kept cool; and the nineral acids, from their known utility in every fpecies of hamorrhagy, ought alfo to be prefcribed. Relt of body is here alfo propcr ; and opiates, when indicated ejther by pain or Spafmodic aftections of the mufcles, ought never to be omitted.

Together with thefe remedies adapted to the general fyftem, particular dreflings, appropriated to the fate of the parts to which they are to be applied, have been found very beneficial. In healthy conftitutions, toon after the \({ }^{\text {n }}\) difcharge of blood is over, the parts ase covered with a vilcid coagulable effufion from the mouths of the now retracted arteries; but in conflitutions of an oppofite nature, where the folids are much relaxed, the blood in general is found in fuch an attenuated fate as to afford no fecretion of this nature.

To fupply as much as poffible the deficiency of this natural balfam, different artificial applications have been invented. Dulting the part with farch or wheat-Hour has fometimes been found of ufe, and gum arabic in fine pouder has been known to anfwer when thefe failed.

Applications of this kind, indeed, have been ufed with fuccefs in all fuch hæmorrhagics, with whatever habit of body they happen to be connected; but they have always proved more particularly ferviceable in relaxed conftitutions, attended with an attenuated fiate of the blood and an enfeebled mufcular fynem. Alcohol, or any other ardent firits, impregnated with as great a quantity as they can diffolve of myrrh, or any other of the heating vifcid gums, may be here ufed with freedom, though in conftitutions of an oppofite mature they ought never to be employed. The balfamum traumaticum of the ftops, a remedy of this nature, has long been famous for its influence in fuch cafes: but that indifcriminate ufe of this and fimilar applications which has long prevailed with fome practitioners, has undoubtedly done much harm ; for as they are all poffefled of very fimulating powers, they of courfe tend to aggravate every fymptom in wounds connceted with a tenfe fate of fibres, or much pain, efpecially when fpafmodic mufcular affections prevail.

By a due perfererance in one or other of the plans here pointed out, it will feldom happen that hæmorrhagies are not at laft put a ftop to: but when the contrary does occur, when, notwithflanding the ufe of the remedies recommended, a difcharge of blood fill continues; in addition to the means already advifed, an equal moderate preffure ought to be applied over the whole furface of the fore, to be continued as long as the neceflity of the cafe feems to indicate.

In finilhing the dreflings of fuch wounds, after the adhefive plafter and compreffes have been applied, a bandage properly adapted to the part ought to be employed, and in fuch a manner as to produce as equal a degree of preffure over the furface of the wound as poffible. But it now and then happens that no bandace can be applied fo as to produce the defired effect ; and in fuch cafes the hand of an affitant is the only refource; which being firmly preffed over the drefings, will commonly fucceed when no other mcans is found to have much influence.

\section*{\(W\) O U \([753] \quad W \quad O \quad U\)}

Wounds of the nerves, tendons, and ligaments, are attended with much more violent fymptoms than thofe where even confiderable arteries are divided, and they frequently refilt cvery method of cure propofed by the moft filful practitioncrs. In the fimple procefs' of blood-letting, it frequently happens that the tendinous expanfion called the aponeurofis of the biceps mufcle is wounded, or even the tendon of that mufcle itfelf is punctured, by the point of the lancet; or fometimes a nerve which happens to lie in the neighbourliood is partially divided. Any one of thefe wounds, though they are the fmalleft we can well fuppofe to be given, are frequently very dangerous and difficult of cure. It fometimes immediately happens on the introduction of the lancet, that the patient complains of a moft exquiSite degree of pain; and when this occurs, we may reft aflured that either a tendon or a nerve has been wounded. On fome occafinns, by proper management, fuch as evacuating a confiderable quantity of blood at the orifice newly made, by keeping the part at perfect reft, and preferving the patient in as cool a flate as poffible, the pain at firft complained of will gradually abate, and at laft go off entirely without any bad confequence. At other times, however, this pain which occurs inftantaneoully on the introduction of the lancet, inftead of abating, begins foon to increafe; a fullnefs, or fmall degree of fwelling, takes place in the parts contiguous to the wound; the lips of the fore become fomewhat hard and inflamed; and, in the courfe of about 24 hours from the operation, a thin watery ferum begins to be difcharged at the orifice.

If, by the means employed, relief is not foon obtained, thefe fymptoms generally continue in nearly the fame flate for two or perhaps three days longer. At this time the violent pain which at firf took place becomes ftill more diftreffing; but inftead of being tharp and acute as before, it is now attended with the fenfation of a burning heat, which goes on to increafe, and proves, during the whole courfe of the ailment, a fource of conftant diffrefs to the patient. The fullnefs and hardnefs in the lips of the wound begin to increafe, and the fwelling in the neighbouring parts gradually extends over the whole members. The parts at lait become exceedingly tenfe and hard; an eryfipelatous inflammatory colour frequently appears ovar the whole member; the pulfe by this time is generally very hard and quick; the pain is now intenfe, the patient exceedingly reftlefs; twitchings of the tendons occur to a greater or lefs degree; on fome occafions, a locked jaw and other convulfive affections fupervene; and all thefe fymptoms continuing to increafe, it rnoft frequent. ly happens that the torture under which the patient has been groaning is at laft terminated by death.

Different opinions have prevailed refpecting the caufe of thefe fymptoms. By fome they have been imputed to wounds of the tendons. By others the tendons are fuppofed to be fo entirely deffitute of fenfibility, as to be guite incapable of producing fo much diffrefs; fo that wounds of the nerves they confider, on all fuch occafions, as the true caufe of the various fymptoms we have mentioned.

One or other of thefe ideas continued to be the only fource for explaining the various phenomena found to occur in this malady, till a different opinion was fuggefted by the late ingenious \(\mathrm{M}_{\mathrm{I}}\) John Hunter of Lon-

Vol. XX. Part 11.
don. Mr Hunter fuppofed, that all the dreadful fymp- Wrouris. toms found now and then to be induced by the operation of blood-letting, might be more readily accounted Vr Juha for from an inllamed ftate of the internal furface of the Hunter'n vein, than from any other caufe. Such a flate of the opinum vein he has often traced in horfes that have died of fuch fymptoms from venefcetion, and the fame appearance, have fometimes occurred alfo in the human budy. And on other occafions, inflammation having in this manner been once excited, has been known to terminate in fup. puration; and the matter thus produced being in the courle of circulation carried to the heart, Mr Hunter fuppofes that in fuch cafes death may have been induced by that caufe alone.
'There can be no rcafon to doubt the fact held forth by Mr Hunter, that in fuch inftances the vein in which the orifice has been made, has frequently after death been found sreatly inflamed: but however ingenious his arguments may be for concluding that the flate of the vein is the original caufe of all the bad fymptoms enumerated, and although we mult allow that fuch an inflammatory affection of a vein mutt have a confiderable influence in aggravating the various fymptoms previoully induced by other caufes; yet we may very fairly conclude, that it could not probably in any one inflance be able to account with fatisfaction for their firft production.

In many cafes the patient, at the very inftant of the operation, feels a very unulual degree of pain. In fome cafes, the violence of the pain is almont unfupportable. Now this we can never fuppofe to have been produced by the mere puncture of a vein; for although the coats of veins are not perhaps entirely deftitute of feeling, yet we know well that they are not endowed with fuch a degree of fenfibility as to render it probable that fuch intenfe pain could ever be induced by theis being punctured in any way whatever. This inflamed fate of not jun. the veins therefore, as detedted by Mr Hunter after death, mult be confidered rather as being produced by, than as being productive of, fuch affections; and that fuch ailments fhould frequently produce an inflammation of the contiguous veins, is a very probable conjecture. In the courle of 48 hours from the operation, when the febrile fymptoms are juft commencing, fuch a degree of hardnefs and evident inflammation is induced over all the parts contiguous to the orifice, that it would be furprifing indeed if the vein, which is thus perbaps entirely furrounded with parts highly inflamed, fhould ef- , IG cape altogether. We flall therefore proceed upon the Really ow. fuppofition of this irflamed flate of the veins being a ing to the confequence rather than the canfe of fuch ailments; and partial of courle we now revert to one or other of the opinions wounding long ago adopted on this fubject, that all the train of of a nerve bad fymptoms found on fome occafions to fucceedivenefection, proceeds either from the wound of a nerve or of a tendon.

That a partial wound of a nerve will now and then produce very dittreffing fymptoms, no practitioner will deny: but it has been attempted to be fhown, that tendons are almoft totally deftitute of fenfibility; and it has therefore been fuppofed, that their being wounded can never account fos the various fymptoms known to occur in fuch cafer. There is great reafon however to think, that in different infances the fame train of fymp. toms have been induced by different caules; that in one 5 C inflance

\section*{W O U [ 754\(] \quad \mathrm{W} O \quad \mathrm{U}\)}

Wounds. infiance a wounded nerve, and in others pricks of the tendons, have given rife to them, as we have already fuppofed.

Tethod of obviating the: © fynup tow.es, and furing the woun!.

In order to prevent as much as poffible the coneeque:at imlammation and other fymptoms which ufually enfue, a confiderable quantity of blood ihould be immediately difcharged at the orfice juit made : the limb, fur feveral days at leaft, ought to be kept in a ltate of per eet reff, care being at the fame time taken to keep the mulfles of the part in as relaxed a flate as poffible : the patent thuld be allo kept cool, on a low diet; and, if neceffary, gentle lasatives ought to be adminiftered.

When, notwithflanding thefe means, the fymptoms, infead of diminiming, rather become more violent; if the lips of the orfice turn hard and more inflmed, if the pais become more confiderable, and efpecially if the fwelling begin to fpead, other remedics come to be indicated. In this tate of the complaint, topical blood leting, by means of leeches applied as near as poftible io the lps of the wound, frequently affords much relief; and when the pulfe is full and quick, it cren becomes noc. flary to evacuate large quantities of blood by opening a vcin in fome other patt.

The external applications ufually employed in this fate of the complant are warm cmollient fomentations ard pu'tices. In fimilar affections of other parts no remerlies winh which we aie acquanted would probably le th und more fuccefsful; but in the complaint now un 'er confid rarion, ail fuch applications, inflead of being productive of ary advantage, rather do harm. The heat of the part is here one of the moft diftrefing fymptors ; ard warm emollient applications rather tend to augment this fource of uncafinefs. The lips of the wound alin are rendered thill more hard, fwelicd, and of courfe niore painful; and the livelling of the contiguous pats is increafed. The bett external remedies are cooling aftingen'e, efpecially the faturnine applications. The parts chiefly ffected being alternately covered over with cloths wet with a folution of faccharum faturni, and pledgers' fpread with Goulard's cerate, are kept more cool and eafy than by any other remedy hitherto ufed. The rebrile fymptoms which occur mut at the fane time be attended to, by keeping the patient cool, on a low dict, prefersing a lex tate of the bowels; and, if neceltary, farther quantities of blood ought to be evacuated.

On account of the violence of the pain, which is fometimes fo escefive as to deftroy entirely the patient's relt, opiales ought to be freely cahibited; and when twitchings of the tendons and other convulfive fymptoms fupervene, madicines of this kind become ftill more neceffary. In order, however, to have a proper influcnce in this ftate of the complaint, opiates ought to be given in very full dofes; othersife, inftead of anfrering any good purpole, they confantly tend to aggravate the different Cymploms, not only by incteafing the heat and refleffnefs, but by having an evident inAucnce in renderisg the fyetem more furceptible than it was before of the pain and other diffrefing effects produced upon it by the nound.

It ofien haprens, however, either from ncgleding the wound or fiom improper treatment, that all thefe remecies are bad reccu:fe :o without any advantage whatcrer: the fever, pain, and fwelling of the parts conti-
nue, and convulfive affections of the mufcles at laft oc. Whounds cur, all tending to indicate the molt imminent danger. In this fituation of maters, if we have not inmediate recourfe to fome effectual means, the patient will loon fall a viaim to the dilorder; and the anly remedy from which much real advantage is to be expected, is a free and extenfive divifon of the parts in which the orifice producing all the mifchief was at firf made. We hnow well, from the experience of ages, that much more pain and diltrefs of every kind are commonly produced by the partial divifion either of a nerve or of a tenden, than from any of thefe parts being at once cut entirely acrols. Now the intention of the operation hete recommended, is to produce a complete divifion of the nerve or tendon we luppofe to have becn wounded by the point of the lancet, and which we confider as the fole caufe of all the fublequent diltrefs.

This oneration being attended with a good deal of pain, and beling put in practice for the remoral of fymptoras from which it is perhaps dificult to perfuade the patient that much danger can occur, all the remedies we have mentioned fhould be nade trial of before it is propofed : but at the fame time, care ought to be taken that the diforder is not allewed to proceed too far before we have recourfe to it; for if the patient fhould be previoully much weakened by the feverifh fymptoms having continued violent for any length of time, neither this rerredy nor any other with which we are acquainted would probably have much intluence. As foon, therefore, as the courle already prefuibed has been fairly tried, and is found to be inadequate to the effects expected from it, we ought immediately to have recourfe to a free divifion of the parts affected.

Wherever a wounded or suptured tendon may be Treatment fituated, the linib fhould be placed in fuch a manner as of wounte will moft readily admit of the setracted ends of the ten-or ruptured don being brought together ; and when in this fituation, \({ }^{\text {tendous }}\) the mufcles of the whole limb in which the injury has happened runft be tied down with a roller, fo as to prevent them from all kinds of exertion during the cure, endeavouing at the fame time to keep the parts eafy and relaxed. Thus, in a wound or ruplure of the tendon of the reelus mufcle of the thigh, the patient's leg hould be kept as much as polfible ttretched out during the cure, while the thigh thould be in fome degree bent, to relax the mufcle itiflf as far as poflible.

In fimilar affections of the tendo Achillis, the kneefhould be kept conftantly bent to relax the mufcles of the leg, and the foot thonld be fretched out to admit of the ends of the ruptured tenden being brought into contact. A roller hould be applied with a firmnefs quite fufficiont for fecuring the mufcles and tendons in this filuation; but care muf be taken to prevent it from impeding the circulation. With this view, foft fine fiannel Ahould be preferred either to linen or cotton; for being more elaftic, it more readily yichs to any fwelling with which the limb may be allacked.

The late Dr Monro was the firft who gave any accurate directions for the treatment of rupture in the large iendons; and it is perhaps given with more precifion, from his having himfelf experienced the (ffects of this misortune in the tendo achillis.

He ufed a foot-fock or flipper, made of double quilted ticking, and left open at the tre; from the beel of rhich a frap went up above the calf of the leg. \(\Lambda\)
frong piece of the fame materials went round the calf, and was faftened with a lace. On the back part of this was a buckle, through which the flrap of the foot-fock was pafied, by which the calf could be brought down, and the fout extended at pleafurc. Defilles there was a piece of tin applied to the fure part of the leg, to prevent the foot from getting into any improper pofture during fleep. After propofing to walk, he put on a thoe with a heel two inches deep; and it was not till the expiration of five months that he ventured to lay afide the tin plate; and he continued the ufe of the high-heeled floce for two years.

From this treatment a knowledge may be formed of the treatment necefiary to be followed in the laceration of teadons of other parts of the budy.

In wounds of the thoras, even though none of the vifcera fhould be wounded, we may yet reafonably expet that a confiderable quantity of blood will be extravalated; and this, if very large, mull be evacuated if pollible. However, it ought to be particularly obferved, that this extravafated blood ftoould not be difcharged before we are affired that the wounded veffels have done bleeding. When the pulfe appears fufficiently ftrong and equal, the extremities warm, no hickup or convulfion, and the patient's firength continues, we may then know that the internal hae norrhagy has ceafel, and that the means for difcharging the blood may now be fafely ufed. Matter, water, and blood have fometimes vanithed from the cavilies of the thorax, and been afterwards difcharged by fiweat, urine, \&sc. Yet this but feldom happens; and if we were to truf to nature alone in thefe cafes, it is certain that many would perith from a deftruction of the vital vifcera by the extravafated blood, who by an artificial extraction of the fame blood might have been faved.

Wounds of the abdomen mun be clofed as foon as poffible, and then treated as fimple wounds; only they ought to be drefled as feldom and expeditioufly as poffible. Copious bleeding and a fpare diet, with other parts of the antiphlogiftic regimen, are here ablolutely neceffary.

It fometimes happens, that, through a large wound of the ahdominal integuments, the inteltine comes out without being injured. The mof certain method, in all fuch cafes, is to return the protruded part as foon as poffible; for although writers in general formerly recommended warm fomentations, \&ic. to be previoully applied, the latelt authors upon this fubject confider the moft natural and proper fomentation to be that which is produced by the heat and moiflure of the patient's belly, and that therefore the inteflinas; if no mortification lias taken place, are to be cleared from extraneous matter, and immediately returned.

When the wound of the abdomen is large, the inteltines eafily prolapfe, and they are as eafly returned. But when part of an inteftine has been forced through a narrow wound, it is much more dangerous. For the prolapfed intefline being diftended by flatus, or the ingefted aliments diriven thither by the periftaltic motion, it will become inflamed, tumefied, and incapable of being returned through the fricture of the wound; whence gangrene will foon follow. In this cafe the utmoft care is to be taken to reduce the inteftine to its natural fize. When this cannot be accomplifted by other means, fome practitioncrs of grcat eminence have even
advifed the puncturing of the iateltine in difierent phaces Weurse in order to difcharge the liatus. 'I his pract ce has allo \(\underbrace{-\quad-\quad}\) been recommended in an incarcerated hernia, but is ex. ceedingly diatuprowed of by Mr l'ott and later writers; and it feems to be very dubious whether any good can pofibly anife from it. To puncture any part that is already inflamed, nulf undoubecdly add to the intli mmation ; and it is very improbable that the difcharge of flatus procured ty the punctures would be at all a recompenfe for the bad confequences produced by the increaled infammation. The method of Colfus i, much more eligible : It is to dilate the wound fo as to reduce the inteltine wits eafe.

Sometimes past of the intefinc is loft either by fuppuration or gangrene. In this cafe, all that can Le done is to put a fingle fitch throu th the wounded bowel, and to fix it to the external wound by pafing the future alfo through the fides of the wound. The ends of the intelline may perhaps adherc ; or at any 1ate the wound will continue to perform the office of an anus, out of which the fexes will continue to be difclarged during life. The directions given by fome furgcons about inferting the upper end of the gut into the lower, and flitching them together, are perfectly impraciicable; and even if they were practicable, would certainly produce new mortification, which could not but be fatal.

When the omentum appears prolapfed, the fame gocneral treatment is to be obferved; only that, when it is mortified, the dead part may be fafely extirpated. - TVe ftall conclude the article of abdominal wounds with a cafe from the memoirs of the academy of fciences for the year 1705, which hows that we ought not to defpair, even though the moft defperate fyinptoms thould take place. A madman wounded himfelf in 18 different places of the abdomen. Eight of thefe penetrated the cavity, and injured the contained vifecra; he had a diarrihea, naulea, and vomiting, tenfion of the abdomen, with difficult refpiration and violent fever, fo that his life was defpaired of. During the firf fuur days he was blooded feven times; and during the greatef part of the cure bis diet confifted almoft entirely of tleft-broths, with the addition of fome mild vegetables. By thcfe means he was not only cured of his wounds, but reftored to his right fenfes. Seventeen months after, he went mad again, and threw himfelf over a precipice, by which he was infantly killed. On opening the borly, the wounds were found to have penetrated the middle lobe of the liver, the inteltinum jejumum, and the colon.

Such extraordinary cures are to be imputed, according to the fatisfactory explanation of Mr J. Bell, to the abdomen being perfectly full, and conftantly fubjected to flrong preflure between the diaphragm and abdominal mufcles; which keeps the parts contiguous to a wound clofely applied to it, alfo in fome meafure prevents the difcharge of fæeces or even of blood, and gives an opportunity for a very fpcedy adhefion between the parts.

In wounds of the hend, where the cellular membrane Wound on only is affected, and the aponeurofis and pericranium the head. are untouched, phlebotomy, lenient purges, and the ufe of the common febrifuge medicines, particularly thofe of the neutral kind, generally remove all the threatening fymptoms. When the inflammation is gone off, it leaves on the fkin a yellowin tint and a dry fcurf, which continue until perfpiration takes thern away; and upon the

Ficuals. gemoval of the difeafe, the wound inmediately recovers a healthy afpect, and foon heals without further trouble. But in the worft kind of thefe wounds, that is, where a imall wound paffes through the tela cellulofa and aponeurols to the pericranium, the patient will admit of more free cvacuations by phlebotomy than in the former. In both, the ule of warm fomentations is required; but an emollient cataplafm, which is generally forbid in the eryfipelatous fwellings, may in this latter cafe be ufed to great advantige. Where the fymptoms are not very prefing, nor the habit very inflammable, this method will prove fufficient; but it fometimes happens that the fcalp is fo tenfe, the pain fo great, and the fymptomatic fever fo ligh, that by waiting for the flow effect of fuch means the patient runs a rifk from the continnance of the fever; or elfe the injured aponeurofis and pericranium become loughy, pioduce an abfcefs, and render the cafe both tedious and troublefome. A divifion of the wounded part, by a fimple incifion down to the bone, about half an inch or an inch in length, will moft commonly remove all the bad fymptoms; and if it be done in time, will render every thing elfe unneceflary.

The wounds penetrating into the cavities of the joints do not feem at firf alarming; yet, by expofure to the air, the lining ruembrane of fuch cavities acquires fuch a degree of fenfibility as to endanger life when they are large. As foon therefore as any extraneous body, pufhed into the joint, is removed, the admifion of the external air is to be guarded againft as much as poffible. If the wound be not too large, this may be done by pulling the fkin over the wound of the joint; and, to prevent its retraction, rather adhefive plafter, with proper bandaging, is to be ufed. But when inflammation has come on, repeated and copious blood-letting, together with fomentations, becomes neceffary; and as the pain, in thefe cafes, is apt to be violent, opiates muft be adminiftered; but fhould matter be formed in the cavity of the joint, free vent mult be given to it.

Of contufed and lacerated Wounds. - When the fmall veffels are ruptured by a blow with any hard inftrument without penetrating the fkin , at the fame time that the folid fibres of the part are crufted, the injury is termed a contufion: and when at the fame time the flin is broken, it is termed a contufed and lacerated wound.
blow is fo violent as to rupture the blood-veffels or crufh fome of the large nerves, all the bad confequences \(u\) bich attend fimple wounds of thofe parts will enfue, and they will not be at all allcviated by the circumftance of the 0kiz remaining whole. Hence it is eafy to fee how a contufion may produce ulcers of the worft kind, gangrene, fphacelus, carious bones, \(8: c\). ; and if it happen to be on a glandular part, a fchirrus or cance: is very freçuently found to enfue. Even the vifcera themfelves, efpecially of the abdomen, may be injured by contufions to fuch a degree as to produce an inflammation, gan. grene, or fchirrus, nay inftant death, without rupturing the flin.

Of Gun-fiot Wounds. -Gun-fthot wounds can be confidered in no other light than contufed wounds. In thofe made by a mufket or piftol ball, the firt things to be done are, to extract the ball, or any other extraneous body which may have lodged in the wounded part; and to flop the hemorihagy, if there be an effufion of blood from the rupture of fome confiderable artery.

It is frequently neceffary to enlarge the wound in Extraction order to extract the ball; and if it has gone quite of the ball through (provided the fituation of the part wounded \(\begin{gathered}\text { reign bo. }\end{gathered}\) will admit of its being done with fafety), the wound is to be laid freely open through its whole length; by which means any extraneous body will be more readily removed, and the cure facilitated.

In order to get at the ball, or any foreign matter, the probe is to be ufed as fparingly as poffible : and this muft appear evident to any one who will only confider the nature of the fymptoms attendant on penetrating wounds of the breaft or belly, either from a bullet or Tharp inflrument; the thrufling in a probe to parts under fuch circumftances being unavoidably a frefh ftab on every repetition. Wherever probing is neceffary, the finger is to be preferred as the beft and trueft probe, where it can be uled.

If a ball, or ary other foreign body, happen to be lodged near the orifice, or can be perceived by the finger to lie under the fk in, though at fome diftance from the mouth of the wound, we flould cut upon it and take it out : but when it is funk deep, and lies abfolutely beyond the reach of the finger, it muft appear evident, upon the leaft reflection, that thrufting, firf a long probe in queft of the bullet, and then, as has been likewife practifed a lang pair of forceps, either with or without teeth, iuto a wound of that kind, though with fome certainty to extract it, mult either contufe, or irritate and inflame the parts to a great degree; and confequently do as much, or more, mifchief as the ball did at firt in forcing its paffage to fuch a length. And thould they at the fame time lay hold of any confiderable artery or nerve along with the ball (which can fcarce ever fail of being the cafe), what thocking confequences would attend fuch a proceeding! Nor would attempts of this fort be lefs injurious, if a bullet fhould happen to be lodged in the cavity of the belly or breall. Such attempts are the lefs neceffary, becaufe a great number of infances have occurred, where balls have been quietly lodged in feveral parts of the body, till after many years they have worked themfelves a paffage towards the furface, and were very cafily extracted; and many cafes alfo where balls have been entirely left behind.

In cafc the wound be occafioned by a mulset or pi-
tounts. ftol hoot, and of courfe be fmall, it will be neceflary to dilate the wound without delay, provided the nature of the part will permit of this with fafety: for in wounds near a joint, or in very mombranous or tendinous parts, the knife, as well as forceps, thould be put under fome reltraint; nor hould any more opening be made than what is abfolutely requifite for the free difcharge of the mitter lodged within.

Where the wounded perfon has not fuffered any great lofs of blood, and this is generally the cafe, it will be advifable to open a vein immediately, and take from the arm a large quantity; and to repeat bleeding as circumflances may require, the fecond, and even the third day. Repeated bleedings in the beginning are followed by many advantages. They prevent pain and a good deal of inflammation, lefien any feverilh affaults, and feldom fail to obviate impofthumations, and a long train of complicated fymptoms which are wont otherwife to interrupt the cure, miferably harafs the poor patient, and too often endanger his life. Even where the feverilb fymptoms run high, and there is almolt a cettainty that matter is forming, bleeding, in fuch a Itate, is very frequently of great advantage.
For the firlt twelve days after the wound has been received, it will be proper to obferve a cooling regimen, both in refpect of the medicines that may be preferibed, and the diet requifite for the fupport of the patient. It is likewife abfolutely neceflary that the body be conftantly kept open. Unlefs, therefore, nature does this office of herfelf, a flool thould be every day procured, either by emollient clyfters, or fome gentle laxative taken at the mouth; and whenever there is much pain in the wounded parts, immediate recourfe muft be had to opium.

As to external applications, whatever is of a hot fpirituous nature is remarkably injurious on thefe occafions, and what no wounded part can in any degree bear. The wound may be dreffed with pledgits of any emollient ointment; the whole being covered with a common poultice, or, in fome cafes, the preparations of lead may be ufed. All opiate fhould now be adminiftered; and the part affected being placed in the eafieft and molt convenient poffure, the patient Mould be laid to reft. The formation of matter, in every contufed wound, is an object of the firft importance; for, till this takes place, there is often reafon to fufpeet that gangrene may happen. With a view to haften fuppuration, the warm poultices fhould be frequently renewed, and they fhould be continued till the tenfion and fwelling, with which wounds of this kind are ufually attended, be removed, and till the fore has acquired a red, healthy, granula. ting appearance, and then it is to be treated like a common ulcer.

Gun-hhot wounds are commonly covered from the beginning with deep floughs, and various remedies are recommended for removing thefe. Every appearance, however, of this kind with which they are attended proceeds entirely from contufion; and, excepting the injury be extenfive, the flough is not often perceptible, or it is fo thin as to come away along with the matter at the firft or fecond drefling. Althougb emollient poultices be extremely ufeful, they ought to be no longer continued than till the effects already mentioned are produced; otherwife they will not only relax the parts, but alfo produce too copious a difcharge of matter, which is
fometimes attended with great danger. A too copious Viourdso flow of nister may procted from difierent caules; but in whatever way it may have been produced, the practice to be adopted muft be niearly the fame. Eivery collection which appears mult have a free outlet, and the limb laid in that poture which will moft readily admit of its running of: In fuch circumfiatices, nourilhing diet and I'eruvian bark in confiderable quantities are highly uleful. When the difcharge continues copious, in fpite of every cffort to check it, detached picces of bone or fome extraneous matier are probably the caule. In fuch a fituation nothing will leffen the quantity of matter till fuch fubflances be removed. The wound ought therefore again to be examined, and any loofe bodies taken away. Pieces of cloth have been known to be removed by fetons, when that method was practicable, after every other method had failed. Opium is frequently ufed in checking an excellive difcharge, when it happens to be kept up by irritation.

Although no confiderable hemorriagy may happen on firtt receiving a gan-flot wound; yet after the floughs commonly produced upon fuch occafions have come off, fome confiderable arteries may be expofed, and then a dangerous hemorrhagy may enfue. The hemorrhagy is often preceded by a great heat in the injured parts, and with a throbbing pulfatory pain. At this period it may frequently be prevented by plentiful blood-letting, particularly local. But if the hemorrhagy has fairly taken place, and from arteries of confiderable fize, nothing will reffrain it but the proper application of ligatures. As the difcharge in thefe cafes would often prove dangerous before the furgeon could be procured, the attendants fhould be furnilhed with a tourniquet, with directions to apply it, upon the firft appearance of blood.

Till of late years the fcarifying of gun-fhot woundsscrif 29 was a practice which prevailed very univerfally among improper. furgeons; and it was expeeted by this, that the lloughs with which wounds are fometimes covered would fooner feparate, and that the cure would thereby be more readily performed. It is now, however, known, that this practice, inftead of being ufeful, very generally does harm by increafing the inflammation. It thould therefore be laid entirely afide.

When a gun-fhot wound cannot eafily or fafely be laid open from one end to the other, perhaps it may be proper to introduce a cord through the finus. This, however, fhould not be attempted till the firft or inflammatory fate of the wound is over: but when a cord cannot be properly introduced, on account of the fituation or direction of the wound, compreffion may prove equally ufeful here as in cafes of punctured wounds.

Mortification happening after gun-fhot wounds, is to be treated in the fame manner as if it had arifen from Mortificav any other caufe, only bark is not to be promifcuouflytion. ufed; as, in plethoric liabits, it may prove hurtful, though in debilitated relaxed habits it will be extremely uffeful; but even in fuch it fhould nerer be given while much pain and tenfion continue.
Of Wounds and Injurries of the Head producing Frac. tures and Deprefions. - When the brain is comprefied, Symptoms. a fet of fymptoins enfue, cxtrenely dangerous, though of comprecifometimes they do not make their appearance tillfion of the after a confiderable interval. But at whatever time \({ }^{\text {brain. }}\) they appear, they are uniformly of the fame kind, and

\section*{W O U}
are in general as follows: drowfinefs, giddinefs, and flupefaction, dimnefs of fight, dilatation of the pupil; and, where the injury done to the head is great, there is commonly a difchange of blood from the eyes, nofe, or ears. Simetimes the fractured bone can be difcovered through the integuments, at other times it cannot. There is an irregular and oppreffed pulfe, and fnoring or apoplectic flertor in breathing. There is likewife naufea and vamiting, with an involuntary difcharge of faces and urine. Among the mufeles of the extremities and other parts, there is lofs of voluntary motion, convullive tremors in fome parts of the body, and palfy in others, efpecially in that fide of the body which is oppofite to the injured past of the head.

Some of the milder of thefe fymptoms, as vertigo, fupefaction, and a temporary lofs of fenfibility, are frequently induced by flight blows upon the head, but commonly foon dilappear, either by reft alone, or by the means to be afterwards pointed out. But when any other lymptoms enfue, fuch as dilatation of the pupils, and efpecially when much blood is difcharged from the eyes, nof, and cars, and that there is an involuntary difcharge of fæees and urine, it may be reafonably concluded that compreffion of the brain is induced.

The cavity of the cranium, in the healthy and natural tiate, is everywhere completely filled by the brain; whatever therefore diminifhes that cavity, will produce a comprefion of the brain.

The canfes producing fuch a diminution may be of various kinds, as fracture and depreffion of the bones of the cranimm; the forcible introduction of any extraneous body into the cavity of the cranium; effufion of blood, ferum, pus, or any other fuid; the thicknefs and irregularity of the bones of the cranium in certain difeafes, as in lues venerea, rickets, or fima ventola; or water collected in hydrocephalous cafes. The firt fot of caufes thall be confidered in their order. The four laft mentioned belong to the province of the phyfician, and have been confidered in a former part of this work.

Fractures of the cranium have been differently diftinguified by different authors; but it feems fufficient to divide them into thofe attended with depreftion, and thofe which are not.

In fracture and depreffion of the cranium, the treatment ought to be,-to difcover the fituation and extent of the fracture; and to obviate the effccts of the injury done to the brain, by raifing or removing all the deprefled parts of the bone.

When the teguments correfponding to the injury done to the bone are cut or lacerated, and, as is fometimes the ca?e, entirely removed, the flate of the fractuse is immediately difcovered; but when the integuments of the foll remain entire, even though the general fymploms of fracture be prefent, thele is fometimes much difficulty in afcertaining it. When, however, any external injury appears, particularly a tumor from a recont contufion, attended by the fymptoms already defcribed, there can be no doubt of the exiftence of a fractuc. But it Cometimes happens that compreffion exifts without the fmallef appearance of tumor. In fuch cafes, the whole head ought to be flaved, when an inflammatory foot may frequently be obferved. Somctimes the place of the fracture has been difcovercd by the patient apply-
ing the hand frequently on or near fome particular part Woumb: of the liead.

When the fymptoms of a comprefled brain are evidently marked, no time ousht to be loit in fetting abrul an examination of the fate of the cranium, whereever appearances point out, or even lead us to conjecture, in what part a fracture may be fituated. Foc this purpofe an incifion is to be made upon the fpot through the integuments to the furface of the bone, which muft be fufticiently expofed to admit of a free examination.

Some authors have recommendsd a crucial incifion ; others one in form of the letter 1 ; while many advife a confiderable part of the integuments to be entirely removed. But as it is more agreeable to the prefent mode of practice to fave as much of the flin as polfible, a fimple incifion is generally p.eferred, unlefs the fracture run in different directions, and then the incifion mult vary accordingly. It will frequently happen, that a confiderable part of the integuments mult be feparated from the Rull, in order to obtain a diftinct view of the full extent of the fiacture; but no part of the integuments is to be entirely remaved.

When blood-veffels of any confiderable fize are divided, either before or in time of the examination, they ought to be allowed to bleed freely, as in no cafe whatever is the lofs of blood attended with mere advantage than the prefent. When, however, it appears that the patient has loft a fufficient quantity, the voffels ought to be fecured.

After the integuments have been divided, if the \(\AA\) wil be found to be fractured and depreffed, the nature of the cafe is rendered evident; but even where there is no external appearance of fracture, tumor, difcoloration, or other injury, if the patient continue \(t s\) labour under fymptoms of a comprefled brain, if the pericranium has been feparated from the bone, and efpecially if the bone has loft its natural appearance, and has acquired a pale white or dunky yellow hue, the trepan ought to be applied without hefitation at the place where thefe appearances mark the principal feat of the injury.

Again, although no mark either of fracture or of any difeafes underneath fhould appear on the outer table of the bone, yet there is a polfibility that the inner table may be fractured and deprefled. This indeed is not a common occurrence, but it happens probably more frequently than furgeons have been aware of; and where it does happen. the injury done to the brain is as great, and attended with as nuch danger, as where the whole thicknefs of the bone is beat in. The application of the trepan is therefore necefliry.

But if, after the application of the trepan, it happers that no mark of injury appears either in the outer or inner table in that part, or in the dura mater below it, and that the fymptoms of a comprefted brain fill continue, a fracture in fome other part is to be fufpesfed ; or that kind of fracture termed by practitiones counter fiffure, where the flull is fractured and fometimes deprefo fed on the oppofite fide to, or at a diflance from, the part where the injury was received. This is fortunately nat a very frequent occurrence, and has even bcen doubled by fome; but different inffances of it have beyond all queftion, been found. If therefore the operatiun of the trepan has been performed, and no fracture
is difcovered, no extravalation appears on the furface of the brain; and if blood-letting and other means ufually emply yeu do not renove the lymptoms of comprefion, the opera or is to foarch for a fiacture on lome other part. 'The whole head thould again be examined with much accuracy; and, by prefling deliberately but firmly over every part of it, il the lmallell degree ol fenfbility remains, the patient will thow figns of pain, either by msans or ly raiting his hands, when prefture is inade over the fractured part. In this way fractures have been frequentiy detceted, which night otherwife have been concealed.
Having now confidered cevery thing preparatury to the opcration of the trepan, we thall next point out the means beit adapted for the rcroval or clevation of a depreffed portion of the bone.

The firll thing to be done is, after having the head, to muke an iacifion as deep as the bons, and directly upon the courle of the fracture.

The patient ought to be laid on a table, with a mattrefs under him, while his head is placed upon a pillow, and fecured by an affitant. When the extent of the fracture has been determined, and the bleeding from the inciion flopped, the deprefled bone is now to be elevated; but previous to this it is necellary to fearch for rletacned pieces. Slould any be found, they ought to be removed by a pair of forceps adapted to this purpoic. By the fame intrument any fplinters of bone which may have been beaten in may be removed; but when a part of the bone is beaten in beyond the level of the reft of the cranium, as much of the peicranium is then to be removed by a ralpatory, as will allow the trephine to be applied; or, if the operator incline, for the fake of difpatch, he may ure the trepan; or the operation may be begun and finifhed with the trephine, while the trepan may perform the middle and principal patt of the work. This part of the work is begun by making a hole with the perforator, deep enongh to fix the central pin of the trephise, in order to prevent the fas from flipping ont of its central courfe, till it has formed a groove fufficiently deep to be worked fteadily in ; and then the pin is to be removed. If the bone be thick, the teeth of the faw muf be cleaned now and then by the bruth during the perforation, and dipped in oil as often as it is cleaned, which will confiderably facilitate the motion, and render it more expeditious; making it at the fame time much leis difagreeable to the patient, if he poffefs his fenfes. That no time may be loft, the operator ought to be provided with two inftruments of the fame fize, or at leaft to have two heads which can be readily fited to the fame handle.

After having made fome progrefs in the oncration, the groove ought to be frequently cxamined with a picktooth, or fome fuch inftrument, in order to difcover its depth; and if one fide happen to be dceper than the other, the operator ought to prefs more on that fide which is thallowef. Precautions are more particularly neceflary when the operation is performed unon a part of the fkull which is of an unequal thicknefs, efpecially
after the inftrument lias paffed the diplos. And though it be faid by writess in general that the influment may be worked buldly till it comes at the diploe (which is generally known by the appearance of blood), yet the operator fhould be upon his guard in this point, cxamining fram time to time if the prece be loafe, left through inadvertence the dura mater be wounded; for in fome parts of the kull there is naturally very litte diploc, and in old fubjects farcely any. It ought likewife to be remembered, that the fkulls of children are very thin. When the piece begins to vacillate, it uught to be fnapped off with the forceps or levator; for the fawing ought by no means to be continued till the bone be cut quite through, otherwife the influment may plunge in upon the brain, or at leaft injure the dura mater ( \(B\) ). If the inner e:Ige of the perforation se left ragged, it is to be fmoothed with the lenticular, to prevent it from irritating the dura mater. Particular care is to be taken in ufing the intrument, left it flould prefs too much upon the bram.

The next thep is to raite the depreffed part of the bone with the levator, or to extrad the fragments of the bone, grumous blood, or any extraneous body. After this, if there appear reafon to apprehend that blood, lymph, or matter, is contained ander the dura mater, it ought to be catuoully opened with a lancet, cadcavouring to avoid the blood-veffels running upon it, or lying inumediately under it.

When the trepan is to be ufed on account of a fillure in which the bone will not yield, the inftrument fioould be applied fo as to include part of ir, if not directly over it, as it is moft probable that the extravafate! Ruid will be found directly under it. And when the fffure is of great extent, it may be proper to make a perforation at each end, if the whole can be conveniently brought into view; and in fome cafes feveral perforations may become necelfary.

When it is propofed to make feveral perforations to remove depreffied fragments of the bone which are firmly fixed, and having the intemal furface larger than the external, or to raife them fufficiently, it is neceflary to apply the trepan as near the fractured parts as polfible; making the per.orations juin each other, to prevent the trouble of cutting the intermediate faces.

When the Rkull is injured over a future, and \(i_{i}\) is no thought advifable to ufe the trepan, a perforation ought to be mande on each fide of the future, efpecially in young fubjects, in which the dura mater adheres more ftrongly than in adults; becaufe there cannot be a free commanication between the one fide and the other, on account of the attachment of that membrane to the fi:ture.

Affer the elevation of the depreffed pieces, or the re-Trearmeni moval of thofe which are quite loofe, the extraction of of the paextranemus bodies, and the evacuation of extravafated tient atrer fuids, \&sc. the fore is to be drefled in the lightell ard the operaeafief manner; all that is necefiary being to apply a pledget of fine fcraped lint, covered with fimple ointment, to that part of the dara mater which is laid bare
(E) A trepanning inftument has been invented by MTr Rodman, furgeon, Paifley, which has no central pin, and it is fo contrived that any given thicknefs of bone may be cut, fo that the danger from other influments is by the ufe of this entirely avoided. See a more detailed acconth of this ictrument under Abapriston.

\section*{W O U}

Wuunds. by the trepan, or otherwife ; after which the edges of the fca!p are to be brought together or nearly fo, and another pledget laid along the whole courfe of the wound; a piece of fine foft linen is to be laid over all, and the dreflings may be retained in their place by a common night-cap applied clole to the head, and properly fixed.

The patient is to be placed in as eafy a pofition in bed as poffible, with his head and fhoulders elevated a little more than ordinary. If the operation be attended with fuccefs, the patient will foon begin to flow favourable fymptoms; he will foon how figns of increafing fenfibility, and the original bad fymptoms will gradually difappear. After this he ought to be kept as quiet as poffible; proper laxatives are to be adminiftered, and fuch as may be lealt of a naufeating nature. His food ought to be fimple and eafy of digeftion, and his drink of the moft diluent kind. If he complain of the wound being unealy, an emollient poultice thould be immediately applied, and rencwed three or four times in the twenty-four hours. By thefe means there will commonly be a free fuppuration from the whole furface of the fore.

Every time the wound is dreffed, the purulent matter ought to be wiped off from it with a fine warm fponge; and if any degree of floughinefs take place on the dura mater or parts adjacent, it will then be completely feparated. Granulations will begin to form, which will continue to increafe till the whole arife to a level with the furface of the cranium. The edges of the fore are now to be dreffed with cerate ftraps, and the reft of it covered with fine foft lint, kept gently preffed on by the night-cap properly tied. In this way the cure will go on favourably; luxuriance of granulations will commonly be prevented; the parts will cicatrize kindly; and as all the k in has been preferved in making the firf incifion, the cicatrix will be but little obferved.

But things do not always proceed in this favourable manner. Sometimes in a few hours after the operation the patient is feized with a kind of refleffuefs, toffing his arms, and endeavouring to move himfelf in bed, while the fymptoms of a compreffed brain remain nearly the fame as formerly. In this cafe, efpecially if the pulfe be quick and Arong, the patient ought to be bled freely, as there will be reafon to fufpect fome tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the fymptoms are not relieved, on account of extravafated Huids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in thefe cales will be in proportion to the depth of the collection. Particular attention therefore ought always to be paid to the ftate of the dura mater after the perforation has been made. If blood he collected below the dura mater, this membrane will be found tenfe, dark coloured, clattic, and even livid; in which cafe, an opening becomes abfolutely neceflary to difcharge the extravalated fluid. Gentle fcratches are to be made with a fcalpel, till a probe or directory can be introduced; upon which the membrane is to he fufficiently divided in a longitudinal, and fometimes even in a crucial direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner,
there is fome danger of the brain protruding at the opening; but the danger from this is not equal to the bad effects arifing from effuled tluids comprefling the brain.

A troublefome and an alarming appearance now and then follows the operation of the trepan; namely, the excrefcences called fungi, formerly luppofed to grow immediately from the furtace of the brain, but which, in general, originate from the lurface of the dura mater or cut edge of the bone granulating too luxuriantly.

It often happens that they pollefs little fenfibility ; and then the beft method to prevent their rifing to any great height is to touch them frequently with lunar cauftic: but fome cales occur where their fenfibility is fo great that they cannot be touched, unlefs they hang by a fmall neck; and then a ligature may be put round them, and tightened from time to time till they drop off, which will commonly be in the courfe of a few days. It feldom happens, however, that there is any oceafion for applying fuch means for the removal of thefe tumors, for they generally fall off as the perforations of the bone fill up.

If they do not, as the connection between them and the brain will be then in a great meafure intercepted, they may be with more fafety removed, either by excifion, by caultic, or by ligature.

The cure being thus far completed, only a fmall cicatiix will remain, and in general the parts will be nearly as firm as at firlt : but when much of the integuments have been feparated or deftroyed, as they are never regenerated, the bone will be left covered only by a thin cuticle, with fome fmall quantity of cellular fubfance. When this is the cafe, the perfon ought to wear a piece of lead or tin, properly fitted and lined with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practifed in cafes of compreffion; but it frequently happens, that inftead of compreffion, fuch a degree of concuftion takes place that no affitance from the trepan can be attended with any advantage; for the effects of concuffion are totally different from thofe of compreffion, and therefore to be removed in a different manner.

Wounds, in Farriery, See Farriery Index.
IVRASSE, or Old Wife. See Labrus, IchthyoLogy Index.

WREATH, in Heraldry, a roll of fine linen or filk (like that of a Turkift turban), confifting of the colours borne in the efcutcheon, placed in an achievement between the helmet and the crelt, and immediately fupporting the crett.

WRECK, or Shipwreck, the deftruction of a hip by rocks or fhallows at fea.

By the ancient common law, where any hip was loft at fea, and the goods or cargo were thrown upon the land, the 1 e goods, fo wrecked, were judged to belong to the king: for it was held, that, by the lofs of the Mip, all property was gonc out of the original owner. But this was undoubtedly anding forrow to forrow, and was confonant neither to reafon nor lumanity. Wherefore it was firf ordained by King Henry J. that if any perfon efcaped alive out of the fhip, it fhould be no wreck ; and afterwards King Henry II. by his charter, declared, that if on the coafts of either England, Puictou, Oleron, or Gafcony, any fhip fhould be diffretled,

and

\section*{W R E}
and either man or beaft fhould efcape or be found therein alive, the goods hhould remain to the owners, if they claimed them within three months; but otherwife fhouid be efteemed a wreck, and fhould belong to the king, or other lord of the franchife. This was again confirmed with improvements by King Richard I.; who, in the fecond year of his reign, not only ettablihed thele conceffions, by ordaining that the owner, if he was hhipwrecked and efcaped, omnes res fuas liberas et quietas haberet, but allo, that if he perifhed, his children, or in default of them, his brethren and fifters, thould retain the property; and in default of brother or filter, then the goods thould remain to the king (A). And the law, as laid down by Bractun in the reign of Henry Ill. feems ftill to have improved in its equity. For then, if not only a dog (for inftance) efcaped, by which the owner might be difcovered, but if any certain mark were fet on the goods, by which they might be known again, it was held to be no wreck. And this is certainly moft agreeable to reafon; the rational claim of the king being only founded upon this, that the true owner cannot be afcertained. Afterwards, in the firft It atute of Weftminfler, the time of limitation of claims, given by the charter of Henry II. is extended to a year and a day, according to the ufage of Normandy : and it enacts, that if any man, a dog, or a cat, efcape alive, the veffel fhall not be adjudged a wreck. Thefe animals, as in Bracton, are only put for examples; for it is now held, that not only if any live thing efcape, but if proof can be made of the property of any of the goods or lading which come to thore, they thall not be forfeited as wreck. The flatute further ordains, that the fleriff of the county thall be bound to keep the goods a year and a day (as in France for one year, agreeable to the maritime laws of Oleron, and in Holland for a year and a half), that if any man can prove a property in them, either in his own right or by right of reptefentation, they fhall be reftored to him without delay; but if no fuch property be proved within that time, they then flall be the King's. If cue goods are of a perifhable nature, the fheriff may fell them, and the money Thall be liable in their ftead. This revenue of wrecks is frequently granted out to lords of manors as a royal franchife; and if any one be thus intitled to wrecks in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and day.

It is to be obferved, that, in order to conftitute a legal wreck, the goods muft come to land. If they contimue at fea, the law difinguifthes them by the barbarous and uncouth appellations of jetfam, fotfan, and ligan. Jet fam is where goods are calt into the fea, and there fink and remain under water: flotfam is where they continue fwimming on the furface of the waves: ligan is whese they are funk in the fea, but tied to a cork or buov, in order to be found agaim. Thefe are alfo the King's, if no owner appears to claim them ; but if any owner appears, he is intitled to recover the poffeffion.

Vol. XX. Part II.

For even if they be eafl overboard, wi:hout any mart: or buoy, in order to lighten the thip, the owne: is not by this aft of necelfity conftrued to have renounced his property: much lefs can things ligan be luppoled to be abandoned, fince the owner has done all in this power to affert and retain his property. Thefe three are therefore accounted fo far a dittnct thing from the former, that by the king's grant to a man of wrecks, thinge jetfam, thotfam, and ligan, will not puts.

Wrecks, in their leggal acceptainon, are at prefent not very frequent: for if any gouds cone to land, it rarely happens, fince the improvement of conamerce, navigation, and correfpond:race, that the owner is not able to affert his property within the year and day limited lig law. And in order to preferve this property entire for him, and if puffible to prevent wrecks at all, our laws have made many very humane regulations; in a fpirit quite oppofite to thole firige laws which formerly prevailed in all the northern regions of Europe, and a few years ago were ftill faid to fubfift on the coalts of the Beltic fea, permitting the inhabitants to feize on whatever they could get as lawful prize; or, as an author of their own exprefles it, "in naufragorum mifera at calamitate tanquam vultures ad predam currete." Vor by the ttatute 27 Edw . III. c. 13 . if any thip be loft on the fiore, and the goods come to land (which cannot, fays the ftatute, be called wreck), they (luall be prefently delivered to the merchan's, paying only a realonable reward to thofe that faved and preferved them, which is intitled falvage. Alfo by the common law, if any perfons (other than the theriff) take any goods fo caft on thore, which are not legal wreck, the owners might have a commiffion to iuquire and find them out, and compel them to make reftitution. And by 12 Ann. flat. 2. c. 18. confirmed by 4 Geo. I. c. 12 in order to affin the diftreffed, and prevent the fcandalous illegal practices on fome of our fea-coafts (too fimilar to thofe on the Baltic), it is enacted, that all head-officers and others of towns near the fea, fhall, upon application made to them, fummon as many hands as are neceffary, ard fend them to the relief of any fhip in diftrefs, on forfeiture of 1001 .; and in cafe of affitfance given, fal. vage thall be paid by the owners, to be affeffed by three neighbouring juftices. All perfons that fecrete any goods thall forfeit their treble value; and if they wil. fully do any act whereby the fhip is lott or deftroyed, by making boles in her, fealing her pumps, or otherwife, they are guilty of felony without benefit of clergy. Laftly, by the fatute 26 Geo. II. c. I9. plundering any veffel, either in diftrefs or wrecked, and whether any living creature be on board or not (for whether wreck or ntherwife, it is clearly not the property of the populace), fuch plundering or preventing the efcape of any perfon that endeasours to fave his life, or wounding him with intent to deftroy him, or putting out falle lights in order to bring any veffel into danger, are all declared to be capital felonies; in like manner as the dellroying of trees, fleeples, or other flated fea-marks,

5 D
is
(A) In like manner Conflantine the Great, finding that by the imperial law the revenue of wrecks was given to the prince's treafury or fifcus, reftrained it by an edift (Cod. 11.5.1.) and ordered them to remain to the owners; adding this humane expoftulation: "Quod enim jus habet fifcus in aliena calamitate, ut de re tam luctuofa compendium fectetur."

\section*{W R E [ 562 ] W R I}

Wrect is punifhed by the fatute 8 Eliz. c. 13. with a forfe:II Wreftling ture of 1001 . or outlawry. Moreover, by the flatute of Geo. II. pilfering any goods caft afmore is declared to be petty larceny; and many other falutary regulations are made, for the more effectually preferving thips of any nation in diltefs.

By the civil law, to deflroy perfons mipwrecked, or prevent their faving the flup, is capital. And to Atcal even a plank from a veffel in diftrefs or wiecked, makes the party liable to anfwer for the whole fhip and cargo. The laws alfo of the Wifigoths, and the molt early Neapolitan conftitutions, punifhed with the utmof feverity all thofe who neglected to affift any hip in diftrefs, or plundered any goods caft on hote.

WREN. See Motacilla, Ornithology Index.
Wren, Sir Chrifopher, a great philotopher, and one of the mof learned and moft eminent architects of his age, was the fon of Chritiopler Wren dean of Windfor, and was born in 1632 . He fludied at Wadham college in Oxford; where he took the degree of mafter of arts in 1653 , and was chofen fellow of All Souls college. When very young he difcovered a furprifing genius for the mathematies; in which fcience he made great advances before he was fisteen years old. In 1657, he was made profeffur of aftronomy at Greham college, London; which he refigned in 1660 , on his being chofen to the Savilian profefforfhip of aftronomy in Oxford : he was next year created doctor of laws, and in 1663 was elected fellow of the Royal Society. He was one of the commiffioners for the reparation of St Paul's; and in 1665 travelled into France, to examine the moft beautiful edifices there, when he made many curious obfervations. "At his return to England, he drew a noble plan for rebuilding the city of London after the fire, which he prefented to parliament; and upon the deccafe of Sir John Denham in 1668 , was made furvcyor-general of his majefty's works; and from that time had the direction of a great number of public edifices, by which he acquired the higheft repuation. He built the magnificent theatre at Oxford, Si Paul's cathedral, the churches of St Siephen Walbrook, and St Mary-le-Bow, the Monument, the modern part of the palace of Hampton Court, Chelfea college, one of the wings of Greenwich hofpital, and many other beautiful edifices. He was prefident of the Royal Society, one of the commiffioners of Chelfea college, and twice member of parliament; firf for Plymouth in Devonflire, and then for Melcomb Regis in the fame county; but in 1718 was removed from his place of Surveyor-general. He died in 1723, and was interred in the vanlt under St Paul's.

This great man alfo diftinguithed himfelf by many curious inventions and difcoveries in natural philefophy; and, among many others, contrived an inftrument for meafuring the quantity of rain that falls on any face of land for a year; be invented many ways of making aftronomical obfervations more accurate and eafy; and was the firt author of the anatomical experiment of in. jecting liquars into the veins of animals, \&e. He tranflated into Latin Mr Oughtred's Honologiogroplica Geometrica; and wrote a Sorvey of the cathedral church of Saliftury, and other pieces. After his death his ponthumous works and draughts were publifhed by his fon.

WLISTLING, a lind of combat or engagement
between two perfons unarmed, body to body, to prove Wi. Qitrg their Itrength and dexterity, and try which can throw lis opponent to the ground.

Wreftling is an excercife of very great antiquity and fane. It was in ufe in the heroic age; witnefs Hercules, who wrefled with Antwus.

It continued a long time in the highen repute, and had confiderable rewards and honcurs affigned to it at the Olympic games. It was the cuftom for the athletæ to anoint their bodies with oil, to gire the lefs hold to their antagonifts.

Lycurgus ordered the Spartan maids to wrelle in public quite naked, in order, as it is obferved, to break them of their too much delicacy and nicenels, to make them appear more robult, and to familiarize the people, \&c. to fuch nudities.

WRIST, in Anatomy. See there, \(\mathrm{N}^{\circ} 53\).
WRIT, in Lau', figraties, in general, the king's precept in writing under feal, iffuing out of fome court, directed to the fheriff or other officer, and commanding fomething to be done in relation to a fuit or action, or giving commiffion to have the fame done. And, according to Fizzherbert, a writ is faid to be a formal letter of the king in parchment, fealed with his feal, and directed to fome judge, officer, or minitter, \&xc. at the fuit of a fubject, for the caufe brietly expreffed, which is to be determined in the proper coort according to law.

Whits, in civil actions, are either original or judicial : original, are fuch as are iflued out of the court of chancery for the fummoning of a defendant to appear, and are granted before the fuit is commenced, in order to begin the fame; and judicial writs iffue out of the court where the original is retumed, after the fuit is begun. See Process.

The original writ is the foundation of the fuit. See Suit.

When a perfon hath received an injury, and thinks it worth lis while to demand a fatisfaction for it, he is to confider with himfelf, or take advice, what redrefs the law has given for that injury; and thereupon is to make application or fuit to the crown, the fountain of all juftice, for that particular fpecific remedy which he is determined or advifed to purlue. As for money due on bond, an action of debt; for goods detained without force, an action of detenue or trover; or, if taken with force, an action of trefpafs viet armis; or, to try the title of lands, a writ of entry or action of trefpafs in ejectment ; or for any confequential injury received, a fecial action on the cafe. To this end he is to fue out, or purchafe by paying the ftated fees, an original or original writ, from the cou:t of chancery, which is the offcina juflitic, the hop or mint of juftice, wherein all the king's writs are framed. It is a mandatory letter from the king in parchment, fealed with his great feal, and dirested to the fteriff of the county wherein the injury is committed, or fuppofed fo to be, requiring him to command the wrong-doer or party accufed, either to do juftice to the complainant, or elle to appear in court, and anfwer the accufation againf him. Whatever the Aheriff does in porfuance of this wat, he mult return or certify to the ccurt of common-pleas, together with the writ itfelf: which is the foundation of the jurifdiction of that court, being the king's warrant for the judges to proceed to the determination of the caule. For it was a maxim introduced by the Normans, that there floould
be tho proceedings in common-pleas befure the king's junices without his original writ; becaufe they held it unfit that thofe juffices, being only the fubfitutes of the crown, fhould take cognizance of any thing but what was thus exprcfily referred to their judgement. However, in fmall actions, below the value of forty flilliags, which are brought in the court-baron or county-court, no royal writ is neceflary; but the foundation of fuch fuits continue to be (as in the times of the Saxoms), not by original writ, but by plaint; that is, by a private memorial tendered in open court to the judge, whercin the party injured fets forth his caufe of action : and the judge is bound of common right to adminifter juttice therein, without any fpecial mandate from the king. Now indecd even the royal writs are held to be demandable of common right, on paying the ufual fces: for any delay in the granting them, or letting an unulual or exorbitant price upon them, would be a breach of magna chitta, č. 29. " nulli vendemus, nulli negabinus, aut difeeremus jutitiam vel rectum."

Original writs are either optional or peremptory; or, in the language of our law, they are either a pracipe or a fote fecerii focurum. The proccipe is in the alternative, commanding the defendant to do the thing required, or thow the realon wherefore he hath not done it. The ufo of this writ is where fomething certain is demanded by the plaintiff, which is in the power of the defendant himfelf to perform ; as, to reftore the poffeflion of land, to pay a certain liquidated debt, to perform a fpecific covenant, to render an accotnt, and the like; in all which cafes the writ is drawn up in the form of a praccupe or command, to do thus, or fhow caufe to the contrary ; giving the defendant his choice to redrefs the injury or ftand the fuit. The other fpecies of original writs is called a fi fecerit te fecurum, foom the words of the writ; which direets the fheriff to caufe the defendont to appear in court, without any option given him, provided the plaintiff gives the fheriff fecurity effectually to profecute his claim. This writ is in ufe where nothing is feccifically demanded, but only a falisfaction in general ; to obtain which, and minifter complete redrefs, the intervention of fome judicature is neceffary. Such are writs of trefpafs, or on the cafe, wherein no debt or other fpccific thing is fued for in certain, but only damages to be affeffed by a jury. For this end the defendant is immediately called upon to appear in court, provided the plaintiff gives good fecurity of profecuting his claim. Both fpecies of writs are tefted, or witneffed, in the king's own name; "witnefs ourfelf at Weftminfter," or wherever the chancery may be held.

The fecurity here fpoken of, to be given by the plaintiff for profecuting his claim, is common to both writs, though it gives denomination only to the latter. The whole of it is at prefent become a mere matter of form; and John Doe and Richard Roe ere always returned as the flanding pledges for this purpofe. -The ancient ufe of them was to anfwer for the plaintiff, who in cafe he brought an action without caufe, or failed in the profecution of it when brought, was liab'e to an amercement from the crown for raifing a falle accufation; and fo the form of the judgement fill is. In like manner, as by the Gothic conftitutions no perfon was permitted to lay a complaint againft another ni/2 fub fcriptura aut ferificatione trium tefium, quod actionem
vellet perfequi: and, as by the laws of Sancho I. king of Portugal; damages were given againft a plaintifi whu profecuted a groundlefs action.
'Ihe day on which the delendant is ordered to appear in court, and on which the therifl is to bring in the writ, and report how far he has obeyed \(i\), is called the return of the writ; it being then relurned by him to the king's jurlices at Weftmialler. And it is always made returnable at the diflance of at leaft 15 days frum the date or teft, that the defendant inay lave time to come up to Wellminfter, even frum the mof remuie parts of the Kingdom; and upon fome eldy in une of the four terms, in which the court lits for the difpatch of bufinefs.

WhITING, the art or act of fignifying and conveying our ideas to othere, by letters or cloaracters wifible to the cyc. .See Composition, Gramaar, and Lavo guage.

The mof ancient remains of writing, which have been tranfmitted to us, are upon hard lubftances, fuch as ttones and metals, which were ufed by the ancients for ediets and matters of public notoricty; tho decalogue was written on two tables of ftone; but this practice was not peculiar to the Jews, for it was ufed by moft of the caltern nations, as well as by the Greeks and liomans; and therefore the ridicule which Voitaire attempts to call upon that part of the book of Genefis, where the people are commanded to write the law on ftones, is abfurd; for what is there faid by no means implies, that other materials might not be ufed on common occafions. The laws penal, civil, and ceremonial, among the Greeks, were engraven on tables of brafs which wete called cyrbes.

We find that wood was alfo ufed for writing on in different countries. In the Sluanian library ( \(\mathrm{N}^{-0} 48 \mathrm{j2}\) ) are fix fpccimens of Kufic writing, on boards about two feet in length, and fix inches in depth. The Chinefe, before the invention of paper, wrote or engraved with in iron tool upon thin boards or on bamboo. Pliny fays, that table books of wood were in ufe before the time of Humer. Thefe table books were called by the Romans pugillares. The wood was cut into thin flices, and finely plained and polihed. The writing was at firf upon the bare wood, with an iron imerument called a nyle. In later times thefe tables were ufually waxed over, and written upon with that inftument. The matter written upon the tables which were thus waxed over was eafily effaced, and by fmoothing the wax new matter might be fubflituted in the place of what had been written before. The Greeks and Romans continued the ufe of waxed table-books long after the ufe of papyrus, leaves, and fkins, became common, becaufe they were fo convenient for correcting extemporary compo. fitions.

Table books of ivory are ftill ufed for memorandums, but they arc commonly written upon with black lead pencils. The practice of writing on table-books covered with wax was not entirely laid afide till tbe commencement of the \(14^{\text {th }}\) century.

The bark of trees was alfo ufed for writing by the ancients, and is fo fill in feveral parts of Afia. The fame thing may be faid of the leaves of trees. It is needlefs to obferve the ufe of parchment and vellum, papyrus and paper, for writing; it is too well known.

14risu Writing

\(\qquad\)

\(\qquad\)
\(\qquad\)

Writing. The method of fabricating thefe fubitances has been already defcribed as they occurred in the order of the alpiabet.

It is obvious, that when men wrote, or rather engraved, on hard fubitances, inftruments of metal were neceffary, fuch as the chifel and the flylus; but the latter was chielly ufed for writing upon boards, waxed tablets, or on bark.

When the ancients wrote on fofter materials than wood or metal, other inftruments were ufed for writing wihh, of which reeds and canes feem to have been the firt. Reeds and canes are fill uled as inftruments for writing with by the 'lartars, the Indians, the Perfians, the Turks, and the Greeks. Pencils made of hair are ufed by the Chincle for their writing: they firf liquefy their ink, and dip their pencils into it. Hair-pencils have likewife been ufed for writing in Europe. Large capital letters were made with them from the time of the Roman emperors till the 16 th century. After the invention of printing they were drawn by the illuminators. Quills of geefe, fwans, peacocks, crows, and other birds, have been ufed in thefe weltern parts for wriking with, but how long is not eafy to afcertain. St Ifidore of Seville, who lived about the middle of the 7 th century, defcribes a pen made of a quill as ufed in his time.

Method of reforing decayed WRITINGS. In the 77th volume of the Phil. Tranf. there is a paper on this fubject by Sir Charles Blagden. One of the beit methods he found upon experiment to be, covering the letters with ohlogifticated or pruffic alkali, with the addition of a diluted mineral acid; upon the application of which, the letters changed very fpeedily to a deep blue colour, of great beauty and intenfity. To prevent the fpreading of the colour, which, by blotting the parchinent, detracts greatly from the legibility, the alkali mould be put on firt, and the diluted acid added upon it. The method found to anfwer bel: has been, to fpread the al. kali thin with a feather over the traces of the letters, and then to touch it gently, as nearly upon or over the letters as can be done with the diluted acid, by means of a feather or a bit of fick cut to a blunt point. Though the alkali hould oceafion no fenfible change of colour, yet the moment the acid comes upon it, every trace of a letter turns at once to a fine blue, which foon acquires its full intenfity, and is beyond comparifon Aronger than the colour of the original trace had been. If, then, the corner of a bit of blotting paper be carefully and dexteroufly applied near the letters, fo as to imbibe the fuperfuous liquor, the ftaining of the parchment may be in a great meafure avoided; for it is this fuperfluous liquor which, abforbing part of the colouring matter from the letters, becomes a dye to whatever it touches. Care mult be taken not to bring the blottiag paper in contand with the letters, becaufe the colouring matter is foft whilf wet, and may eafily be rubbed off. The acid chiefly employed was the marine; but bath the vitriolic and nitrous fucceed very well. They thould be fo far diluted as not to be in danger of corrodirg the parchment, after which the degree of fliength does not feem to be a matter of much sicely.

Method of Copying ITRITING. The ingenious Mr Watt, fome years ago, invented a method of copying wsitings very fpcedily, and without the poffibility
committing miftakes. A piece of thin unfized paper is to be taken exactly of the fize of the paper to be co. pied; it is to be moittened with water, or, what is better, with the following liquid: T'ake of ditilled vine. g.r two pounds weight, difialve it in one ounce of boracic acid ; then take four ounces of oyfter-fhells calcincd to whitenefs, and carefully freed from their brown crult; put them into the visegar, flake the misture frequently for 24 hours, then let it ftand until it depofits its fediment; filter the clear part through unfized paper into a glafs veflel; then add two ounces of the belt blue Aleppo galls bruifed, and place the liquor in a warm place, fhaking it frequently for 24 hours; then filter the liquor again through unfized paper, and add to it after filtration one quart, ale meafure, of pure water. It mult then fland 24 hours, and be filtered again if it thows a difpofition to depofit any fediment, which it gencrally does. When the paper has been wet with this liquid, put it between two thick unfized papers to abforb the fuperfluous moifture; then lay it orer the writing to be copied, and put a piece of clean ivriting paper above it. Put the whole on the board of a rol-ling-prefs, and prefs them through the rolls, as is done in printing copperplates, and a copy of the writing fhall appear on both fides of the thin moiltened paper \(;\) on one fide in a reverfed order and direction, but on the other fide in the natural order and direction of the lines.

WRITTEN mountains. See Mountains.
WRY-neck. See Jynx, Ornithology Index.
WURTEMBURG, or Wirtenberg, a fovereign duchy of Germany, in Suabia; bounded on the north by Franconia, the archbifhopric of Mentz, and the palatinate of the Rhine; on the eaft by the county of Oeting, the marquifate of Burgau, and the territory of Ulm; on the fouth by the principality of Hoen-Zollern, Furtenburg, and the marquifate of Hohenburg; and on the weft by the palatinate of the Rhine, the marquifate of Baden, and the Black Forelt. It is 65 miles in length, and as much in breadth, and the river Neckar runs almolt through the middle of it from fouth to north. Though there are many mountains and woods, yet it is one of the molt populous and fertile countries in Germany, producing plenty of grals, corn, fruits, and a great deal of wine towards the confines of the palatinate. There are alfo mines, and falt fprings, with plenty of game and filh. It contains 645 villages, 88 towns, and 26 cities, of which Stutgard is the capital.

IVURTSBURG, a large bimopric in Germany, com. prehending the principal part of Franconia. It is bounded by the county of Henneburg, the duchy of Coburg, the abbey of Fuld, the archbiflopric of Mentz, the marquifate of Anlpach, the bilhopric of Bamberg, and the county of Wertheim; being about 65 milcs in length, and 50 in breadth, and divided into 50 bailiwicks. The foil is very fertile, and produces more corn and wine than the inhabitants confume. The territories of the bifhop comprehend above 400 towns and villages, of which he is fovereign, being one of the greateit ecclefiaftical princes of the empire.

WURTZRURG, a large and handfome city of Germany, and one of the principal in the circle of Franconia. It is defended with good fortifications, and has a magnificent palace. There is a handfome hofpital, in
uttaire, which are generally 400 poor men and women. The ycherley. cafle is at a linall diftance from the city, and commands it, as it flands upon an cminence. It communicates with the city by a flonc bridge, on which are 12 thatues, reprefenting as many faints. 'The arfenal and the cellars of the bifhop delerve the attention of the curious. There is alfo an univerlity, founderl in 1403. It is feated on the river Maine, in E. Long. 10. 2. N. J.at. 49.40 .

WYCHERLEY, William, an eminent Emglifh conic poet, was born about 1642 . A little before the reftoration of King Charles II. he became a gentleman commoner of Queen's college Oxford, where he was reconciled by Dr Barlow to the Proteftant religion, which he had a little before abandoned in his travels. He afterwards entered himfelf in the Middle-temple, but foon quitted the fludy of the law for purfuits more agreeable to his own genius, as well as to the tate of the age. Upon writing his firf play, entitled, Love in a Wood, or St James's Park, which was asted in 1672 , he became acquainted with feveral of the celebrated wits both of the court and town, and likewife with the duchefs of Cleveland. Some time after appeared his comedies, called The Gentleman Dancing Matter, the Plain Dealer, and the Country Wife; all which were acted with applaule. George duke of Buckingham had a very high efteem for him, and beftowed on him feveral advantageous polts. King Charles alfo howed him fignal marks of favour ; and once gave him a proof of his efteem, which perhaps never any fovereign prince before had given to a private gentleman. Mr Wycherley being ill of a fever, at his lodgings in Bow-Areet, the king did him the honour of a vifit. Finding him extremely weakened, he commanded him to take a journey to the fouth of France, and affured him, at the fame time, that be would order him 500 . to defray the charges of the journey. Mr Wycherley accordingly went into France ; and having fpent the winter there, returned to England entirely reitored to his former vigour. The king, ihortIy after his arrival, told him, that he had a fon, who he was refolved Thould be educated like the fon of a king, and that he could not choofe a more proper man for his governor than Mr Wycherly; for which fervice 15001. per annum fhould be lettled upon him.

Immediately after this offer he went to Tiunbridge, where walking one day upon the Well's walk with his friend Mr Fairbeard, of Gray's lnn, juft as he canse up to the bookfeller's fhop, the countefs of Drogheda, a young widow, rich, noble, and beatiful, came there to inquire for the Plain Dealer; "Madam," fays Mr Fairbeard, "fince you are for the Plain Dealer, there he is for you;" pulhing Mr WYcherley towards her. "Yes," fays Mr Wycherly, "this lady can bear plain dealing; for the appears to be fo accomplifhed, that what would be a compliment to others, would be plain dealing to her." "No, truly, Sir," faid the countefs, "I am not without my faults, any more than the reft of my fex; and yet notwithtanding, I love plain dealing, and am never more fond of it than when it tells me of them." "Then, madam," fays Mr Fairbeard, "you- and the Plain Dealer feem defigned by Heaven for each other." -In thort, Mr Wycherley walked a turn or two with the countefs, waited upon her home, vifted her daily while fle ftaid at Tunbridge, and married her foon after without acquainting the king. By this flep, which was
looked upon as a contempt of his majefly's orders, he for. Wyclerley feited the royal favour. The countefs of Droylieda fettled her whale fortune upon him; but his title being difputed after her death, he was fo reduced by the expences of the law and other incumbrances, as to be unable to fatisfy the impatience of his creditors, who threw him into prifon; and the bookfeller who printed his Plain Dealer, by which he got almon as much money as the other gained reputation, was foungrateful as to refuife to lend him 201. in his extreme necelfity. In that conlinement he languifled feven years; but at length King lames going to fee the above play, was fo charmed with it, that he gave immediate orders for the payinent of his debts, and even granted him a penfion of 2001 . per annum. But the prince's bourstiful intentions were a great meafure defeated merely through Mr Wycherlcy's modelly; he being aflamed to tell the earl of Mulgrave, whom the king had fent to demand it, a truc flate of his debts. He laboured under the weight of thefe dilficulties till his father died, who left him 6001 . a-year. But this eftate was under limitations, he being only a tenant for life, and not being allowed to raife any money for the payment of his debts. However, he took a method of doing it which few fufpected to be his choice; and this was making a juinture. He had often declared, that be was refolved to die married, though he could not bear the thoughts of living in that Hate again : accordingly, jult ai the eve of his death, he married a young gentlewoman with 1500 . fortune, part of which he applied to the ufes he wanted it for. Eleven days after the celebration of thefe nuptials, in December \(17^{15}\), he died, and was interred in the vault of Coventgarden church.

Befides his plays above mentioned, he publified a volume of poems in folio. In 1728 his pollhumous works in profe and verle were publihed by Mr Theobald.

WYNDHAM, Sir William, defcended of an aft. cient family, was born about the year 1687 , and fuc. cceded young to the title and eftate of his father. On his return from his travels, he was chofent member for the county of Somerfet; in which fation he ferved in the three laf parliaments of Queen Anne, and as long as he lived: after the change of the miniftry in 1710 , he was appointed fecretary at war; and in 1713 was raifed to be chancellor of the exchequer. Upon the breach between the earl of Oxford and Loord Bolingbroke, he adhered to the interelts of the latter. He was removed from his employment on the acceffion of George I. and falling under fufpicion on the breakine out of the rebellion in 1715 , was apprehended. He made his efcape; a reward was publifhed for appreheneing him; trefurrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in oppofition to the feveral adminiftrations under which he lived; and died in 1740.

WYE, a river of South Wales, which iffuing out of Plinlymmon Hill, very near the fource of the Severn, croffes the north-ealt corner of Radnorthire, giving name to the town of Rhyadergowy (Fall of the WYe), where it is precipitated in a cataract : then flowing between this county and Brecknockinire, it crofles Herefordnire, and dividing the counties of Gloucefter and Nonmouth, falls into the mouth of the Severn, below Chepltow: The romantic beatities of the Wye, which flows in a

Wye. deep bed, between lofty rocks clothcd with hanging woods, and here and there crowned by ruined cattles, have employed the defcriptive powers of the pen and pencil.

Wye is alfo the name of a river in Derbythire, which rifes in the north-weft part, above Buxton; and, Howing fouth-erf, falls into the Derwent, below Bakewell.

Wye, the name of a town in Kent, with a market on Thurday, feated on the Stour, 10 miles fouth of Can. terbury, and 59. Couth-eaft of Lordon. E. Long. I. 4. N. Lat. 5 I. 10.

Wye, a lown of Switzerland, in a territory of the abbey of St Gallen, with a palace. It is built on an eminence 16 miles 「outh fouth-wef of Conftance. E. Long. 9. 4. N. Lat. 47. \(34^{4}\).

\section*{X.}

Xonthium

X,or \(x\), is the \(22 d\) letter of our alphabet, and a dou, ble confonant. It was not ufed by the Hebrews or ancient Grecks; for, as it is a compound letter, the ancients, who ufed great fimplicity in their writings, exprefled this letter by its component letters cs. Neither have the Italians this letter, but exprefs it by. If. X begins no word in our language but fuch as are of Greek original; and is in few others but what are of Latin derivation; as perplex, reflexion, defluxion, \&c. We often exprefs this found by fingle letters, as cks, in backs, necks; by ks, in books, breaks; by cc, in accefs, accident; by ct, in action, untion, \&c. The Englifh and French pronounce it like \(c s\) or \(k s\); the Spaniards like \(c\) before \(a\), viz. Alexandro, as it were Alecandro. In numerals it expreffeth 10, whence in old Koman manuferipts it is ufed for denarius; and as fuch feems to be made of two V 's placed one over the other. When a dafh is added over it, thus \(\overline{\mathrm{X}}\), it fignifies 10,000 .

XANTHIUM, a genus of plants of the clafs monccia, and arranged in the natural elaflification under the 49th order, compofite. See Botany Index.

\section*{XANTHOXYLUM. See Zantuoxylum.}

XEBEC, or Zebec, a fmall three-mafted veffel, navigated in the Mediterranean fea, and on the coalts of Spain, Portugal, and Barbary. See Plate fig. 10.

The fails of the sebec are in general fimilar to thofe of the poleacre, but the bull is extremely different from that and almoft every other veffel. It is furnilhed with a Arong prow : and the extremity of the ftern, whicl is nothing more than a fort of railed platform or gallery, prcjects farther behind the counter and buttock than that of any European thip.

Being generally equipped as a porfair, the xebec is conflructed with a riarrow floor, to be more fwift in purfuit of the enemy; and of a great breadth, to enable her to carry a greater force of fail for this purpofe without danger of overturning. As thefe veffels are ufually very low built, their decks are formed with a great convexity from the middle of their breadth toward the fides, in order to carry off the water which falls aboard more readily by their fcuppers. But as this extreme convesity weuld render it very difficult to walk thereon at fea, particularly when the veficl rocks by the agitation of the waves, there is a platform of grating extending ainng the deck from the fides of the reffel towards the middle, whereon the crew may walk dry-footed
whilf the water is conveyed through the grating to the fcuppers.

Xebee

The sebecs, which are generally armed as veffels of Xenocrates. war by the Algerines, mount from 16 to 24 cannon, and carry from 300 to 450 men , two-thirds of whom are generally foldiers.

By the very complicated and inconvenient method of working thefe veffeis, what one of their captains of Algic:s told Mr Falconer will be readily believed, viz. that every xebec requires at ieaft the labour of three fquare-rigged fhips, wherein the fanding fails are calculated to anfwer every fituation of the wind.

XENOCRATES, a celebrated ancient Grecian philofopher, was born at Chalcedon in the 95th Olympiad. At fint be attached himfelf to Efchines, but afterwards became a difciple of Plato, who took much pains in cultivating his genius, which was naturally heavy. His temper was gloomy, his afpeet fevere, and his manners little tinctured with urbanity. Thefe matetial defects his mafter took great pains to correct; Frequently advifing him to facrifice to the Graces : and the pupil was patient of inftruction, and knew how to value the kindnefs of his preceptor. As long as Plato lived, Xenocrates was one of his moft eiteemed difciples; after his death he clofely adhered to his doctrine; and, in the fecond year of the incth Olympiad, he took the chair in the academy, as the fuccefior of Speufippus.

Xenucrates was celcbrated among the Athenians, not only for his wifdom, but for his virtues. So eminent was his reputation for integrity, that when he was called upon to give evidence in a judicial tranfaction, in which an oath was ufually required, the judges unanimoully agreed, that his fimple affervation hould be taken, as a public teftimony to his merit. Even Philip of Macedon found it impoffible to corrupt him. So abftemicus was he with refpect to food, that his provifion was frequently fpoiled before it was confumed. His chaftity was invincible. Phiyne, a celebrated Athenian courtezan, attempted without fuccefs to Ceduce him. Of his humanity the following pathetic incident is a fufficient proot: \(\boldsymbol{A}\) fparrow, which was purfued by a hawk, flew into his bofom: be afforded it protection till its enemy was out of fight, and then let it go, faying, that he would never lelray a fuppliant. He was fond of retirement, and was feldom fcen in the city. He was difcreet in the ufe of Eufieris his time, and carefully allctted a certain portion of each Plifitofol of
day ve!, ii

\section*{X E N}

20erates day to its proper bulinefs. One of thefe he cmployed in filent meditation. He was an admirer of the mathematical fciences; and was fo fully convinced of their utility, that when a young man, who was unacquainted with geometry and aftronomy, defired admiffion into the academy, he refufed his requeft, faying, that he was not yet poffeffed of the handles of philufophy. In fine, Xenocrates was eminent both fur the purity of his morals and for his acquaintance with fcience, and lupported the credit of the Platonic fchool, by his lectures, his witings, and his conduct. He lised to the firt year of the 116 Olympiad, or the 82 of his age, when he lof his life by accidentally falling, in the dark, into a refervoir of water.

XENOPHANES, the fuunder of the Eleaic feet of philofoply among the Greeks, was born at Colophon probably about the 6 th Olympiad. From fome caufe or other he lett his country early, and took refuge in Sicily, where he fuppoted himelelf by reciting, in the court of Hiero, elegiac and iambic verfes, which he had written in reprelienfion of the theogonics of Hefiod and Homer. From Sicily he pafed ovcr into Magna Griecia, where he took up the profeflion of philofophy, and became a celebrated preceptor in the Pythagurean fchool. Indulging, however, a greater freedom of thought than was ufual among the difciples of Pythagoras, he ventured to introduce new opinions of his own, and in many particulars to oppofe the docrines of Epimenides, Thales, and Pythagoras. Xenophanes poffeffed the Pythagorean chair of plilofuphy about feventy years, and lived to the extreme age of an hundred years, that is, according to Eufeibius, till the 8rft Olympiad. The doctrine of Xenophanes concerning nature is fo imperfectly preferved, and oblcurely expreffed, that it is no wonder that it has been differently reprefented hy different writers. Perhaps the truth is, that he held the univerfe to be one in nature and fubfance, but diftinguifhed in his conception between the matter of which all things confift, and that latent divinc force which, though not a diflinet fubftance but an attribute, is neceffarily inherent in the univerfe, and is the caufe of all its perfection.

XENOPHON, an illuftrious philofopher, general, and hiltorian, was born at Athens in the \(3^{d}\) year of the 8 id Olympiad. When he was a youth, Socrates, fruck with his external appearance, determined to admit him into the number of his pupils. Meeting him by accident in a narrow paffage, the philofopher put his flaff acrofs the path, and fopping him, afked, where thofe things were to be purchafed which are neceffary to human life? Xenophon appearing at a lofs for a reply to this unexpected falutation, Socrates proceeded to ank him, where honeft and good men were to be found ? Xenophon fill hefitating, Socrates faid to him, "Follow me, and learn." From that time Xenophon became a difciple of Socrates, and made a rapid progrefs in that moral wifdom for which his mafter was fo eminent. Xenophon accompanied Socrates in the Peloponnefian war, and fought courageoully in defence of his country. He afterwards entered into the army of Cyrus as a private volunteer in his expedition againft his brother. This enterprife proying unforiunate, Xennphon, after the death of Cyrus, advifed his fellow foldiers to attempt a retreat into their own country. They liftened to his advice; and having had many proofs of his wifdom as well as courage, they gave him the command of the army, in the room of Proxenus

\section*{767 ] X I M}
who hat fallen in batt!c. In this command he acraised conducted them back, thruogh the midfl of innumerable dangers, into their own country. The particulars of this memorable adventure are telated by Xenophon himfelf in his lieteat of the Ten 'W.ouland. After his return into Giscece, he juised Agefilaus, king of Sparta, and fought with him againft the 'Thebans in the celebrated batile of Cnieronea. The Athenisans, difpleafed at this alliance, brought a public accufation againft him for his former conduct in engaging i.1 the fervice of Cyrus, and condemned him to exilc. The Spartans, upon this, took Xenophon, as an injared man, under thcir protection, and provided him a comfortable reterat at Scilluntes in Elea. Here, with his wife and two children, he remained feveral years, and pafied his time in the fociety of his friends, and in writing thole hinlurical works which have rendered his name immutal. A war at length arofe between the Spartans and Eleans; and Xenophon was obliged to retire to Lepreus, where his eldett fon had fettled. He afterwards removed, with his whole family, to Corinth, where, in the firft year of the bundred and fifith Olympiad, he finihised his days.
Xerophos the Younger, a Greek writer, fo called to dithinguifin him from the celebrated Xenophon, was bo:n at Ephefus, and livec, according to fome authors, befure Heliodorus, that is, about the beginning of the \(4^{\text {th }}\) century. He is only known by his Ephefiaca, a Greek somance in five books, which is efteemed, and contains the amours or adventures of Abracomes and Anthia. '1 his romance was printed at London, in Greek and Latin, in 1724, 4 to.
XEliXES I. the fifth king of Perfia, memorable for the vaft army he is faid to have carried into the field againft Leoridas king of Spatta ; confifting, according to fome hifloriaus, of 800,000 men, while others make it amount to \(3,000,000\), exclufive of attendarits. The fleet that attended this prodigious land force is liliewife made to confirt of 2000 fail ; and all the fuccefs they met with was the taking and burning the city of Athens; for the arny was hamefully repulfed near the ftraits of Tliermopyle by Leonidas, and the fleet was difperfed and partly deftroyed by Themiftocles at the ftraits of Salamis, who had only 3 So fail under his command. Xerxes was affallinated by Artabanes, chief captain of his guards, and his diftinguihed favourite. See Sp.arta

XIMENES, Francis, a juitly celebrated cardinal, bifhop of Toledo, and prime minifter of Spain, was bern at Torrelaguna, in Old Caflile, in 1437, and ftudied at Alcala and Salamanca. He then went to Rume; and being robbed on the road, brought nothing back but a bull for obtaining the firf vacant prebend : but the archbihop of Toledo refufed it him, and threw him into prifon. Being at length reflored to liherty, he obtained a benefice in the diocefe of Siguença, where Cardinal Gonzales de Mendoza, who was the bihop, made him his grand vicar. Ximencs fome time after entercd among the Francifcans of Toledd'; but being there troubled with vifits, he retired to a folitude named Cafanel, and applied himfelf to the fludy of divinity and the oriental tongues. At his return to Toledo, Queen Ifabella of Cafile chofe him for her confeflor, and aftersards nom: nated him archbithop of Toledo ; which, next to the pafacy, is the richert diguity in the church of Rome. "This honcur (fays Dr Robertion) he declized with a
firmats.

\section*{X I M}

Simenes. firmnefs which nothiag but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. 'Though obliged to difplay in public that magnifieence which became his ftation, he himfelf retained his monallic feverity. Under his poontifical robes he conltantly wore the coarfe frock of St Francis, the rents of which he ufed to paich with lis own hands. He at no time ufed linen, bet was commonly clad in hair-cloth. He flept always in his habit ; miof fiequently on the floor or on boards, and rarely in a bed. He did not talte any of the delicacies which appeared at his tabie, but fatisfied himfelf with that fimple diet which the rule of his order prefcribed. Notwithftanding thefe pcculiarities, fo oppofite to the manners of the world, he poffified a thorough knowledge of its affairs, and difcovered talents for bufinefs which rendered the fame of his wifdom equal to that of his fanctity." His firf care was to provide for the neceffities of the poor ; to vifit the churches and hofpitals; to purge his diocele of ufurers and places of debauchery; to degrade corrupt judges, and place in their room perfons whom he knew to be difinguifhed by their probity and difintereftednefs. He erected a famous univerfity at Alcala; and in 1499 founded the college of St Ildephonfo. Three years after he undertook the Polyglot Bible; and for that purpole fent for many learned inen to come to him at Toledo, purchafed feven copies in Hebrew for 4000 crowns, and gave a great price for Latin and Greek manufripts. At this Bible they laboured above 12 years. It contains the Hebrew text of the Bible ; the verfion of the Septuagint, with a literal tranflation; that of St Jerom, and the Chaldee paraphrafes of Onkelos; and Ximenes added to it a dictionary of the Hebrew and Chaldee words contained in the Bible. This work is called Ximenes's Polyglot. In 1507 Pope Julius II. gave him the cardinal's hat, and King Ferdinand the Catholic entrufted him with the adminiffration of affairs. Cardinal Ximenes was from this moment the foul of every thing that paffed in Spain. He diftinguilhed himfelf at the beginning of his miniftry by difcharging the people from the burdenfome tax ealled acavale, which had been continued on account of the war againft Granada; and laboured with fuch zeal and fuccefs in the converfion of the Mahometans, that he made 3000 converts, among whom was a prince of the blood of the kings of Granada. In 1509 Cardinal Ximenes extended the dominions of Ferdinand, by taking the eity of Oran in the kingdom of Algiers. He undertook this conquert at his own expence, and marched in perfon at the head of the Spanifh army clothed in his pontifical ornaments, and accompanied by a great number of ecclefiaftics and monks. Some time after, forefeeing an extraordinary fcarcity, he erected public granaries at Toledo, Alcala, and Torrelaguna, and had them filled with corn at his own expence; which gained the people's hearts to fuch a degree, that to preferve the memory of this noble action they had an eulogium upon it cut on marble, in the hall of the fenate-houle at Toledo, and in the marketplace. King Ferdinand dying in 1516 , left Cardinal Ximenes regent of his dominions; and the arehduke Charles, who was afterwards the emperor Charles V. confirmed that nomination. The cardinal immediately made a reform of the officers of the fupreme council and of the court, and put a fop to the oppreffion of the gran-
dees. He vindicated the rights of the people againft the Ximener. nobility ; and as by the feudal conflitution the military power was lodged in the hands of the nobles, and neen of inferior condition were called into the field only as their vaflals, a king with fcanty revenues depended on them in all his operations. From this fate Ximenes refolved to deliver the crown; and iflued a proclamation, commanding every city in Caftile to inrol a certain mumber of its burgeffes, and teach them military difcipline; he himfelf engaging to provide officers to command them at the public expence. This was vigoroully oppofed by the nobles; but by his intrepidity and fuperior addref be carried his point. He then endeavoured to diminift the poffefions of the nobility, by reclaiming all the crown-lands, and putting a fop to the penfions granted by the late king Ferdinand. This adcition made to the revenues enabled him to difcharge all the debts of Ferdinand, and to eftablift magazines of warlike ftores. The nobles, alarmed at thefe repeated attacks, uttered loud complaints; but before they proceeded to extremities, appointed fome grandees of the firt rank to examine the powers in conlequence of which he exercifed acts of fuch high authority. Ximenes received them with cold civility; produced the teftament of Ferdinand, by which he was appointed regent, together with the ratification of that deed by Charles. To both thefe they objected; and he endeavoured to eftablifh their validity. As the converfation grew warm, he led them infenfibly to a balcony, from which they had a view of a large body of troops under arms, and of a formidable train of artillery. "Behold (fays he, pointing to thefe, and raifing his voice) the powers which I have received from his Catholic majefty ! With thefe I govern Caftile; and with thefe 1 will govern it, till the king, your mafter and mine, takes poffeffion of his kingdom!" A declaration to bold and haughty filenced them, and aftoninted their affociates. They faw that he was prepared for his defence, and laid afide all thoughts of a general confederacy againt his adminiftration. At length, from the repeated intreaties of Ximenes, and the impatient murmurs of the Spanifh miniftry, Charles V. embarked, and landed in Spain, accompanied by his favourites. Ximenes was advancing to the coaft to meet him, but at Bos Equillos was feized with a violent diforder, which his followers confidered as the effects of poifon. This accident obliging Ximenes to flop, he wrote to the king, and with his ufual boldnefs advifed him to difmifs all the ftrangers in his train, whole number and credit already gave offence to the Spaniards, and earneftly defired to have an interview with him, that he might inform him of the fate of the nation, and the temper of his fubjects. To prevent this, not only the Flemings, but the Spaning grandees, employed all their addrefs to keep Charles at a diftance from Aranda, the place to which the cardinal had remored. His advice was now flighted and defpiled. Ximenes, confcious of his own integrity and merit, expected a more grateful return from a prince to whom he delivered a kingdom more fourifhing than it had been in any former age, and a more extenfive authority than the moft illuftrious of his anceftors had ever poffeffed; and lamented the fate of his country, about to be rumed by the rapacioufnefs and infolence of foreign favourites. While his mind was agitated by thefe pafions, he received a letter from the king; in which, after a few retire to his dineefe; and he expired a lew hours alter reading it in 1517 , in the 81 1t year of his agge.

This famous cardinal ought not to be confuunded with
Roderic XLuIENEs, archbithop of Coledo, in the \(13^{\text {th }}\) century, who wrote a Hitory of Spain in ninc books; nor with feveral other Spanifl writers of the name of Simenes.

XIPHIAS, the Sword-Fish; a genus of filtes belonging to the order of apodes. Ste Lemtirooogy Indew. This fith is common in the Mediterrantan fea, efpecially in that part which feparates Italy from Sicily, and which has been long celebrated for it: the promontory Pelorus, now Capodi Faro, was a piace noted for the refurt of the xiphias, and poflibly the fation of the fpeculatores, or the perfons who watched and gave notice of the approach of the fift.

The ancient method of taking them is particularly defcribed by Strabo, and agrees exactly with that practifed by the moderns. A man afcends one of the clifts that overhangs the fea: as foon as he fies the fith, he gives noticc, either by his voice or by figns, of the courfe it takes. Another that is nationed in a boat, climbs up the maft, and on feeing the fword-fift, dircets the rowers towards it. As foon as be thinks they are got within reach, he defcends, and taking a fpear in his hand, frikes it into the fill ; which, after wearying itfelf with its agitation, is feized and drawn into the boat. It is much cfteemed by the Sicilians, who buy it up eagerly, and at its frit coming into feafon give for it about fixpence Englift per pound. The feafon lafts from May till Auguf. The ancients ufed to cut this fifh into pieces and falt it; whence it was called Tonus Thurianus, from Thurii, a town in the bay of Tarentum, where it was taken and cured.

The fword-fin is faid to be very voracious, and that it is a great enemy to the tunny, which (according to Belon) are as much terrified at it as Theep are at the fight of a wolf. It is a great enemy to whales, and frequently deftroys them.

XYLO-ALOES, or Aloe wood, in the Materia Medica, is the product of a tree growing in China and forne of the Indian illands. See Excecaria.

This drug is diftinguifhed into three forts; the calambac or tambac, the common lignum aloes, and calambour.

The calambac, or fineft aloes wood, called by authors lisnum aloes preflanifimum, and by the Chinefe fukhiang, is the molt refinous of all the woods we are acquainted with: it is of a light fpongy texture, very poruus, and its pores fo filled up with a foft and fragrant refin, that the whole may be preffed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of maftich. This kind, laid on the fire, melts in great parts like refin, and hurns away in a few moments with a bright flame and perfumed fnell. Its fcent, while in the mafs, is very fragrant and agreeable; and its tafte acrid and bitterif, but very aromatic and agrceable. It is co variable in its colour, that fome bave divided it into three kinds; the one variegated with black and putple; the fecond, with the fane black, but with yellowith inflearl of purple : and the third, yellow alone like the yolk of an egg: this latt
is the lean feented of the threc. The variation, how. Xyan aices ever, is owing to the trunk of the thee Leing iffif of thrce different colours; and the heart of it is the va. luable fort firt defaribed. 'the two folloring ate fuppoled to be the other parts of the tumk; thoughts this leems doubiful, efpecially in regard to che lat fort, frome the circumalance mentioned of tha being found in large logs cntire, ind fomelinies only the Fear\%, which, as abuve noticed, conltitutes the calamazac.

The ligsum aloes vulgare is the lecend in veioce. Ihis is of a more denfe and compact texture, and curfiquer.tly lefs refinous than the other; there is lane of it. heseever, that is fungy, and has the holes filied up witl: the right refmus matter; and all ol it, whenged, has veins of the fame refin in it. We meet with it in tmall firssments, which have becn cut and funt isom larger: thele are of a tulerably denfe texture in the snere diflid p:eces, and of a dulky broun coluur, variegated with refincus black veins. It is in this flate very heary, and lefs fragrant than in thofe pieces which thow a multitude of little holes, filled up with the fume blackith matter that. forms the veins in others. The woody nart of thefe lett pieces is lomewhat darker than the other, and is not unfrequently purplifl, or even blackift. The fmell of the common aloe wood is very agreeable, but not follrongly perfumed as the former. Its tatte is fomewhat bitier and acrid, but very aromatic.

The calambour, called allo arallochum fylvelre, and lignum aloes mexicanum, is light and friable, of a defly and often mottled colour, between a dulky green black and a deep brown. Its fmell is fragrant and agrece able, but muclz lefs fweet than that of eiller of the others; and its tafte bitterilh, but not fo much acrid or aromatic as either of the two furmer. 'This is faid to be met with very frequently, and in large logs; and thefe fometincs entire, fonetimes obly the heart of the tree. This is the aloe wood ufed by the cabine.-makers and inlayers.

I'his drug is efteemed a cordial taken inwardly; and is fometimes given in diforders of the tomach and bonels, and to deftroy the worms. A very fragrant oil may be procured from it by dinillation; which is recommended in paralytic cates from five to fifteen drons. It is at prefent, however, but little uled; and would farce be met with anywhere in the thops, but that it is an ingredient in fome of the old compofitions.

XYNOECIA, in Grecian antiquity, en anniverfary fealt obferved by the Athenians in honour of Mincrvas upon the fixteenth of Hecatombæon, to commemorate their leaving, bythe perfualion of Thefeus, their country feats, in which they bay difperfed here and there in Attica, and uniting logether in one body.

XYSTARCHA, in antiquity, the matter or directur of the xyftus. In the Greek gymnafium the syftarcha was the fecond officer, and the gymnafiarcha the firf ; the former was his lieutenant, and prefided over the two xydi, and all exercifes of the athletw therein.

XISTUS, among the Greeks, was a long portico, open or covered at the top, where the athletx prattifed wreitling and ruming: the gladiators, who practifed therein, were called \(x y\) stict. Among the Komanc, the xyffus was only an allej. or double row of trees, meeting like an arbour, and forming a thade to walk under.

Y,or \(y\), the \(23^{d}\) letter of our alphabet: its found is , formed by exprefling the breath with a fudden expanfion of the lips from that configuration by which we exprefs the vowel \(u\). It is one of the ambigenial letters, being a confonant in the beginning of words, and placed before all vowels, as in yard, yield, youns, \&c. but before no confonant. At the end of words it is a vowel, and is fubitituted for the found of \(i\), as in \(t r y\), defery, \&c. In the middle of words it is not ufed fo frequently as \(i\) is, unlefs in words derived from the Greek, as in chyle, empyreal, \&c. though it is admitted into the middle of fome pure Englih words, as in dying, fying, \&c. The homans had no capital of this letter, but ufed the frall one in the middle and laft fyllables of words, as in coryambus, onyx, martyr. Y is alfo a nameral, fignifying I 50 , or, according to Baronius, 150 ; and with a dath a-top, as \(\bar{y}\), it fignified 150,000 .

YACHT, er Уatch, a veffel of ftate, ufually employed to convey princes, ambaffadors, or other great perfonages, from one kingdom to another.

As the priacipal defign of a yacht is to accommodate the paffengers, it is ufually ftted with a variety of convenient apartments, with fuitable furniture, according to the quality or number of the perfons contained therein.

The royal yachts are commonly rigged as ketches, except the principal one refcrved for the fovereign, which is equipped wih three mafts like a flip. They are in general elegantly furnifhed, and richly ornamented with foulpture; and always conmanded by captains in his majefy's navy.

Befides thefe, there are many other yachts of a fmaller kind, employed by the commiffioners of the excife, navy, and cuftoms; or ufed as pleafure-boats by private gentlemen.

\section*{YAMS. See Dioscorea, \\ YAMBOO. See Eugenia, 5 \\ Botany Index.}

YARD of a Ship, a long piece of timber fufpended upon the malts of a hip, to extend the fails to the wind. See Mast and Sail.

All yards are either fquare or lateen; the former of which are furpended acrofs the matts at right angles, and the latter obliquely.

The fquare yards ate nearly of a cylindrical furface. They taper from the middie, which is called the jings, towards the extremities, which are termed the yardarms; and the diffance between the flings and the yardarms on each fide is by the artificers divided into quarters, which are diflinguihed into the firft, fecond, third quarters, and yard-arms. The middle quarters are formed into eight fquares, and each of the end parts is figured likc the fultum of a cone. All the yards of a hhip are fquare except that of the mizen.

The proportions for the length of sards, according to the different claffes of thips in the Britith navy, are as foilows:

1000: gun-deck: : 1000 : main-yard : : \(\left\{\begin{array}{l}581: \\ 880: \\ 877:\end{array}\right\}\) fore-yard. \(\left\{\begin{array}{l}100 ~ \\ 90 \\ \text { all } \\ 80\end{array}\right.\)

To apply this rule to practice, fuppofe the gun-deck 144 feet. The proportion for this Iength is, as 1000 is to 575 , fo is 144 to 83 ; which will be the length of the main-yard in feet, and fo of all the selt.

Guns.
1500: main-yard :: \(\left\{\begin{array}{l}820: \\ 847 \\ 840: \\ 540\end{array}\right\}\) mizen-yari \(\left\{\begin{array}{l}100 ~ 90806044 \\ 70 \\ 27\end{array}\right.\)
 icoo: fore-yarí : : \(\left\{\begin{array}{l}719: \\ 726: \\ 715:\end{array}\right.\), fore topfail-yara \(\left\{\begin{array}{c}70 \\ 74 \\ \text { alt the re:t }\end{array}\right.\) : \(: 00\) : main topfail-yard : : main top gallant-yard all the rates.
 scoo: fore-toprail yard: : \(\left\{\begin{array}{c}765 \\ 750\end{array}\right\}\) mizen topfail yard \(\left\{\begin{array}{c}70 \\ \text { all the ref? }\end{array}\right.\)

Crofs-jack and frit-fail yards equal to the fore top-fail-yard.

Sprit-topfail-yard equal to the fore top-gallant-yard.
The diameters of yatds are in the following proportions to their length.

The main and fore yards five-fevenths of an inch to one yard. The topfail, crofs-jack, and fprit-fail yards, nine-fourteenths of an inch to one yard. The top-gallant, mizen topfail, and fprit-fiil topfail yards, eightthirteenths of an juch to one yard.

The mizen-yard five-ninths of an inch to one yard.
All fludding-fail booms and yards half an inch to one yard in length.

The lifts of the main-yard are exhibited in the above figure by \(g g\); the horfes and their ftirrups by \(h i\); the the reef-tackles and their pendents by \(k, l\); and the braces and brace-pendents by \(n, n\).

The lateen-yards evidently derive their names from having been peculiar to the ancient Romans. They are ufually compofed of feveral picces faftened together by wooldings, which alfo ferve as fteps whereby the failors climb to the peek or upper extremity, in order to furl or caft loofe the fail.
The mizen-yard of a fhip, and the main-yard of a bitander, ate hung obliquely on the maft, almoft in the fame manner as the lateen-yard of a xebec, fettee, or polacre.

YARD, a meafure of length ufed in Britain and Spain, confilting of three fect, chiefly to meafure cloth, flufis, \& c.

CIRD－Arm is that half of the yard that is on either fide of the maft，when it lies athwart the fhip．

Yards alfo denotes places belonging to the navy， Where the ftups of war，\＆c．are laid up in harbour．－ There are belonging to his majefty＇s navy fix great yards，viz．Chatham，Deptford，Woolsich，Portfenouth， Sheernefs，and Plymouth；thefe yards are fitted with feveral docks，wharts，launclies，and graving places，for the building，repairing，and cleaning of his majefty＇s nips；and therein are lodged great quantities of tim－ ber，mants，planks，anchors，and other materials：there are alfo convenient fore－houfes in each yard，in which are laid up vatt quantities of cables，rigging，fails，blocks， and all other forts of ftores needful for the royal navy．
\(\dot{Y} \wedge R E\) ，among failors，implies ready or quick：as， be yare at the helm；that is，be quick，ready，and expe－ ditious at the helon．It is fometimes allo ufed for bright by feamen：as，to keep his arms yare ；that is，to keep them clean and bright．

Yare，a river of Norfolk，which runs from weft to eaf through that county，paffing by Norwich，and fall－ ing into the German fea at Yasmouth．

YrAlMIOUTH，a fea－port town of Norfolk，with a market on Wednefdays and Saturdays，and a fair on Friday and Saturday in Eafter－wcek for petty chapmen． It is feated on the river Yare，where it falls into the fea；and is a place of great ftrength，both by art and nature，being almolt furrounled with water；and there is a drawbrifige over the river：It is eneemed the key of this coatt，and is a clean handfome place，whofe houfes are well built，it being a confiderable town for trade．It has one luge church，and a neat chapel，and the feeple of St Nicholas is fo high that it ferves for a rea－mark．It is governed by a mayor．The harbour is a very fine one，though it is very dangerous for ftrangers in windy weather；and it has for its fecurity a pretty ftrong fort．It is 27 miles eaft of Norwich，and 112 north－eaft of London．E．Long．1．55．N．Lat． 52. 45.

Earvouth，a town of the ile of Wight，in Hamp－ Mire，with a market on Fridays，and one fair on July 25 th for toys．It is feated on the weltern part of the infand，on the fea－fhore，and is encompaffed with water； for，not many years ago a channel was cut through the peninfula，over which there is a drawbridge，and it is defended by a ftrong calle on the quay．It is a hand－ fome place，whofe houfes are chiefly built with fonc， and covered with flate；and it fends two members to parliament．The market is now difufed．W．Long． 1．28．N．Lat．50． 40.

YARN，wool or flax fun into thread，of which they weave cloth．See Clotu．

YARROW．See Achillea，Botany Index．
IAWNING，an involuntary opening of the mouth， grenerally produced by wearinefs or an inclination to fleep．Yawning，according to Boerlaave，is performed by expanding at one and the fame time all the mufcles capable of Cpontaneous motion；by greatly cxtending the lungs；by drawing in gradually and ilowly a large quantity of air ；and gradually and flowly breathing it out，after it has been retained for fome time and rare－ fied；and then reftoring the mufcles to their natural flate．Hence the effect of yawning is to move，acce－ lerate，and çaally difribute all the humours through
all the veffels of the body，and confequently to qualify
the nufcles and organs of fenfation for their various fundions．

Sancturius obferves，that a great deal is infenfibly dif－ charged，when nature endeavours to get rid of the re－ tained perfpirable matter，by yawning and ftretching of the limbs．To thefe a perfon is molt inclined juft after nleep，becaufe a greater quantity going off by the pores of the fkin than at other times，whenfoever a purfon wakes，the increafing contraction that then happeus clofes a great deal of the pertpirable matter in the cuta－ neous paftages，which will continually give fuch irrild tions as encite yawning and ftretching ；and fuch mo－ tions，by haking the membranes of the whole budj， and thifting the contacts of their filtre，and the inclofed matter，by degrees throw it off．Hence we fee the reafon why healthful flrong peopls are mon inclined to fuch motions，becaufe thicy pufpire molt in time of tleep，and therefore have more of the perfpirable matter to lodge in the pores，and greater irritations theremnto． The advantages of fome littie exercife juft after waking in a morning are confiderable，as it throws off all the perfirable matter that is ready for its exit out of the body．When yawning is troublefome，Hippocrates fays that long deep refpiration or drawing in the air at long intervals cures it．

YEAR，in Aflronomy and Cheonology．See Astro－ nomy and Kalendar．

The ancient \(R\) oman year was the lunar year，whicb， as firft fettled by Romulus，confifted of only 10 monshs； viz．I．March，containing \(3^{J}\) days．2．April，30．3． May，31．4．June，30．5．Quintilis，31．6．Sextihs， 30．7．September，30．8．Oहtober，31．9．Nerem－ ber，30．10．Deceniber，30．－In all 304 days；which came thort of the true lunar year by 50 days，and of the folar，by 61 days．Numa Pompilius corrected this irregular conftitution of the year，and compofed two new monthe，January and February，of the days that were ufed to be added to the former year．

The ancient Egyptian year，called allo the year of Nabonafir，on account of the epoch of Nabonaffar，is the folar year of 365 days，divided into 12 months，of 30 days each，befides five intercalary days added at the end．The names，\＆cc．of the months are as follows： 1．Thoth．2．Paophi．3．Athyr．4．Chojac．5．Ty－ bi．6．Mecheir．7．Phamenoth．8．i＇harmuthi．g． Pachen．10．Pauni．11．Epiphi．12．Mefori；befide

The ancient Greek year was lunar；confiting of 12 months，which at firf had 30 days apiece，then alte：－ nately 30 and 29 days，computed from the firf appear－ ance of the new moon；with the addition of an embolif． mic manth of 30 days，every \(3^{\mathrm{d}}\) ， 5 th， 8 th ， \(11 t^{\text {th }}\) 14 th， 16 th，and 19 th year of a cycle of 19 years；in order to keep the now and full moons to the fame terms or feafons of the year．Their year commenced wilh that new moon，the full moon of which comes next af－ ter the fummer folltice．The order，Eic．of their months was thus：1．＇Exurofisxiay，containing 29 days．2．Mz－

 ay，29．8．A⿻essnewor，30．9．E入afribohicar，32． 10. M\＆wntay，30．11．Oxgrndiav，29．12．Sxigepogran 30.

The ancient Jewifh year is a lurar year，confaitns \({ }_{5} \mathrm{E}_{2}\)

\section*{Y E A}

Yepr. carmonly of It monthe, which alternately contain 30 and 29 days. It was made to agree with the folar year, either by the adding of 11 , and fumetimes 12 days: at the end of the year, or by an embolifmic month. The names and quantities of the months fland thus: 1. Nifan, or Abib, 30 days. 2. Jiär, of Zias, 29. 3. Siban, or Siwan, 30. 4. Eliammaz, or Tammuz, 29. 5. Ab, 35. 6. Elul, 29. 7. Tifri, or Ethanim, 30. 8. Marchefvem, or Ihul, 29. 9. C:lleu, 30. 12. T'ebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the embolifmic year, 30 . Adar, in the common year, was but 29. Note, in the defective year, Cillat was ouly 20 da:"s; and in the redundant yeur, Marchefvam was 30.

The Pe fian year is a folar year of about 365 days; conifting of \(1=\) months of 30 days each, with live intercalary days added at the en!.

T'ne itrabic, Mathotan, and Turkih years, called alfo the year of the Hegira, is a lunar year, equal to 354 days eight hours and 48 minutes, and confiffs of 12 montls, which contain alternately 30 and 29 days.

The Hindoo year differs from all thefe, and is indeed d:fiserent in different provinces of India. The beft account that we have of it is by Mr Cavendifh, in the Phil. 'Iranl. of the Royal Society of London for the year 1792. "Before I lpeak of the civil year of the Findoos (fays this eminent philofopher), it will be profer to fay a few words of the altronomical year, by which it is regulated.
" Tle aftonomical year begins at the infant when the fun comes to the fift point of the Hindoo zodiac. I7 the year 1792 , it began on April 9 th, at \(22 \mathrm{~h} .14^{\prime}\) afier midnight of their firft meridian, which is about \(41^{\prime \prime}\) of time weft of Calcutta; but, according to Mr Gentil's sccount of the Indian aft ronomy, it began 3 h. \(24^{\prime \prime}\) earlicr. As this year, however, is longer than ours, its conmencement falls continually later, in refpect of the Julian year, by \(50^{\prime} 26^{\prime \prime}\) in four years. This year is divided into 12 months, each of which correfponds to the time of the fun's flay in fome fign : fo that they are of difercnt lengths, and feldom begin at the beginning of a dey.
"The civii day in all parts of India begins at funtife, ard is divided into 60 parts called davidar, which are axain divided into 60 palas. In thofe parts of India in which the Benares almanac, or as it is there called pa*ras, is ufed, the civil year is lanifolar, confilting of 12 lunar months, with an intercalary month inferted bet oen them occafionally. It begins at the day after the new moon next before the beginning of the folar year. The lunar month is divided into 30 parts called Leelices; thefe are not Arichly of the fame length, but are equal to the tirne in which the moon's true motion from the fun is \(12^{\circ}\). From the new nuoon till the moon arrives at \(12^{\circ}\) ditlance from the fun is called the firt teether ; from thence till it crmes \(102 t^{\circ}\), is ralled the Fecond teetice: and fo out till the full moon, after which ti.e tee hees return in the fame order as before.
"The civil day is conflantly called by the number of Wat tectlice which expires during the courfe of the day; and as the teethee is formtimes longer than one day, a day fomctimes occurs in which no teetbee ende. When this is :he cafe, the day is called by the fame number as the following day: fo that two fucceflive days go by the lame nanne. It oflener happens, however, that two
tecthees and on the fame day; in which eafe the number of the fin of them gives name to the day, and there is no day called by the number of the laft, io that a gap is made in the order of the days. In the latter part of the month the days are counted from the full moon, ia the fame manner as in the former part they :re coumed ficm the new moon; ouly the latt day, or thas on which the new moon happens, is called the 30 oh, inficad of the \(\mathrm{i}^{\text {th }}\). It appeas, therefu:e, that each half of the month confantly hegins on the day after that on which the rew or full moon falls; unly fometin:s the half montt: begins with the fecond day, the firt being wanting.
" This manner of counting the days is fufficiently intricate; but that of counting the months is flill more fo.
" The civil year, as was before faid, begins at the day after the new moon; and, moreover, in the ycars which have an intercalary month, this month begins at the day after the new moon; but notwithfianding this, the ordinary civil month begins at the day after the full moon. To make their method more intelligible, we will call the time from new moon to :erw moon the 11atural month. The civil month Vilathka, the firfl in the Hindoo kalender, which extends from the \(9^{\text {th }}\) of our April to the roth of May, begins at the day after that fuld moon which is nearelt to the inftant at which the fun erters inefha, the firft in order of the Indian figns, whether before or after; however, it is not always accurately the nearef.
"A confequence of this way of counting the mouths is, that the firf half of Chitra, the laft month in the Indian kalender, extending from March the roth to Apzil the gth, falls in one year, and the later haif in the following year ; and whenever the fun euters no fign during a natural month, this month is intercalay. The number of deys in the month varies from 29 to 32. Indeed the Hindoo months, both folar and iuner, confift neither of a determinate number of days, nor are regulated by any cycle, bur depend folely on the motions of the fun and moon; fo that a Hindoo has no way of knowing what day of the month it is but by confulting his almanac; and what is more, the month ought fometimes to begin on different days, in difierent places, on account of the difference in latitude and lottgitude, not to mention the difference which may arife from errors in computation. This mode of computing time muft be attended with many inconveniences; but in the tranfactions of civil life the Hindoos do not much regard it. A difagreement, however, in the computation of the teethce, which fometimes allo happens, occafions no fmall perplexity; becaufe by the teethees or lunar days are regulated moft of their religious feftivals. Every lrahmin in charge of a temple, or whofe duty it is to announce the times for the obfervance of religious ceremonies, is therefore furnithed with one of thsir almanacs; and if he be an aftronomer, be makes fuch corrections in it as the difference of latitude and longitude 1enders nece:fary."

New TEAn's Gifi. See Gift.
YEAS'T, or Yrst, a head or fcum rifing upon bec: or ale while working or ferrirating in the vat. Sce Brewing.

It is ufed for a leaven or ferment in the baking of bread, as ferving to fwell or puff it up very confiderably
pent. in a littie time, and to make it much lighter, fofter, and vmore delicate. Sce Baking, Barv, and Pariais.

Mr Henty has publilliced a method of preparing artificiut yontt, by which good bread may be made without the aflitance of any other ferment. The methed is this: Boil flowe and water tagether to the confillence of treacle, and when the mixture is cold faturate it wilh fixed air. Pour the mixture thos faturated into one or mive large buttles or narrov-mouthed jirs; cover it over lootely with paper, and upon that liny a late or boatd with a weight to keep it lleady. Place the veffel in a lituation where the thumometer will fand from \(70^{\circ}\) to \(80^{\circ}\), and flir up the inixture t:vo or thirce times in 24 hours. In about two days fuch a degree of lermemation will have taken place, as to give the misture the appearance of yeat. With the yeatt in this flate, and before it has acquired a thoroughly vinous finell, mix the quantity of Hour intended for bread, in the proportion of fix pounds of flour to a quart of the yeatl, and a fufficient purtion of warm water. Khead them well tageller in a proper veffel, and covering it with a cloth, let rhe dough !tand for 12 huurs, or till it appears to be fufficiently fermented in the fore-mentioned degrce of warmeth. It is the to be formed intu loases and baked. Mr Henry adds, that perhaps the yeaft would be nore perfect, if a decoction of male were ufed inftead of fumple water.
It has lately been difcoverect, that a decoction of malt alone, without any addition, will produce a yeaft proper enough for the parpole of brewing. This difcuvery was made by Jofepla Senyor, fervant of the reverend Mr Mafon of Affon near Rotheram; and he received for it a reward of 201 . from the Society for promoting Aris, Manufactures, and Commerce. The procels is as folluws: Procure three earthen or wooden veffels of differem fizes and apertures, one capable of holding two quarts, the other three or four, and the third five or fix: boil a quatter of a peck of malt for about eight or ten minutes in three pints of water; and when a quart is poured off from the grains, let it ftand in the firt or finaller veffel in a cool place till not quite cold, but tetaining that degzee of heat which the brewers ufually find to be proper when they begin to work their liquor. Then remove the reffie into fome riarm fituation near a fire, where the thermometer:itands between 70 and 80 degrees Fahrenheit, and there let it remain till the fermentation begins, which will be plainiy perceived vithin 30 hous: add then two quarts more of a like decoction of malt, when cnol, as the firft was; and mix the whoie in the fecond or latger veffel, and fir it well in, which mun be repeated in the ufoal way, as it rifes in a cornmon vat : then add a fill greater guantity of the fame decoction, to be worked in the Jargent reffel, which will produce yenfe enough for a brewing of 40 gailors.
Common ale yeatt may be kept frefh and fit for ufe Several monthe by the following method: Put a quantity of it into a clofe canvas bag, and gently fqueeze out the moifure in a ferew-prefs till the remaining matter be as firm and fliff as clay. In this flate it may be clofe packed up in a tight cafk for fecuring it from the aires and will keep freflh; found, and fit for ufe, for a long time. This is a fecret that might be of great ufe to the brewers' and diflillers, who, though they employ very large quantities of year, feen to know no method
of preferving iv, or raifing nufferies of it; for want of whach they filtain a vely confiderable lofs; whereas the brewets in Flanlers make a very great adventage of fupplying the male dilliilers of Holland with yeaft, which is rendeacd lafting and fit for carrage by this eafy experlient.

YELAL, one of the illands of Shetland, lying northealt Irom the Mainlond, and divided frons it by an atso of the fea, called lell-simend. Hy fome it is thought to have been the Thale of the ancients. In the old defcriptions it is riid to be 20 iniles long and 8 broad. It is very mesunnainous and tull of muls; but. there are pretty confiuerable falfures in which they feed a great mnitiy fincep; mid it alfo affords plenty of peat. It has eight large barbours, which wwuld not be though delpieable it orher conntries. Anciently it feems to bave been pretty populows, fince there are in it three churches, twenty chapels, and many brugls or Pictifn forts.

YELLOW, one of the original colours of light.
YEII.OW-Colour for Houfe-painting. See CoIourMaking.

Naples Telloor, a beautiful colour much ufed by painters, formerly thought to be prepared from arlenic, but now dicovered to have lead for its bafis.
TFi.ion-Hamme: See Friaghia, Ornithology Index.

Telloif-Fever. Sec Medicine, No 168.
YEMEN, a province of Arabia, ftretching along the lied fea and Indian ocean, and forming a part of the country once known by the name of Arabia Felix.
YEOMAN, the firf or ligheft degree among the plebeians of England, next in order to the gentry.

The ytomen are properly freeholders, who having land of their own, live oin good hufbandry.

Yeomax is alio a title of oflice in the king's houfehold, of a iniddle place or rank between an ufher and a gronm.

TEOMEN of the Guard were anciently 250 men of the boil rank under gentry, and of larger flature than ordinary, each being required to be fix feet high. At prefent there are but 100 yeomen in conifant duty, and 7 more not in duty; and as any of the 100 dies, his place is fupplied out of the 70 . 'They go dreffed after the manner of liing Henry VIII.'s time. They formerly had diet as well as wages when in wailing; but this was taken off in the reign of Queen Ame.

Yest, or Yeast. See Yeast.
YEW. See Taxus, Botany Inden.
Yew trees are remarkable for their duration. Thele are now growing within 300 yards of the old Gothic ruins of Fountain's abbey, near Rippon, in Yorkhlire, feven very large yevt trees, commonly called the Seven Siflers, whofe exart ages cannot be accurately alcertained, though tradition fays that they were flanding in the year ro83. It is faid alfo, that when the great Fouktain's albey was building, which is 700 feet long, and was finifhed in 1283 , the mafons ufed to work their flones, during the hot fummers, under the fhade of the trces. The circumference of the Seven Sifters, when meafured by a curious traveller, were of the following fizes:- the fimallett tree, round its body, 5 yards 1 foret; four others are from \(5^{\frac{7}{2}}\) to \(7 \frac{1}{2}\) yards; the fixth is 9 ? yards; and the feventh is 11 yards if foct 7 inclies in. circumference, being 2 yards 10 inches larger than the-

\section*{YO R [ 774\(] \quad\) I \(○ \quad P_{2}\)}
great yew tree now growing in the churchyard at Grepford, in North Wales, which is 9 yards 9 inches. There trees are the largeft and oldell in the Britift dominions.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally fignifying, lord, king, emperor, and royal blood.

YOAK, or Yoke, in Agriculture, a frame of wood fitted over the necks of oxen, whereby they are coupled together, and harneffied to the plough.

Yo. sK of Land, in our ancient cuftoms, was the face which a yoke of oxen, that is, two over, may plough in one day.

YOLK, the yellow part in the middle of an egg (fee EGG). It contains a lymphatic fubftance mixed with a certain quantity of mild oil, which, on account of this mixture, is Soluble in water. When expofed to heat, it afiumes a confiftence not fo hard as the white of the egg; and when bruifed gives out the oil which it contrains. This oil has been unfed externally as a liniment.

YONNE, a river in France, which riling in Burgundy, and running north through Nivernois and Champagne, falls into the Seine at Monterau fur Yonne.

YORK, in Latin Eboracum, the capital of Yorkhire in England. This city is fo ancient that the origin of it is uncertain. In the time of the Romans a legion was flationed here, it being then the capital of the Mrigates; and here died the emperor Severus, and Flavius Valerius Conftantius Chlorus, father of Conftantine the Great. There was then alfo a temple of Bellona here, and no lefs than three military ways went from hence. In the time of the Saxons it was erected into an archbihhopric by Pope Honorius, to which are now fubject the bihoprics of Chefter, Durham, Carlifle, and the ifle of Man; though anciently 12 bifhoprics in England, and all Scotland, wee. A horn is fill kept in the mingler, by which Ulphius, one of the Saxon princes, bellowed all his lands and revenues upon the church.

This city fuffered very much during the ravages of the Danes; but, after the Conqueft, it began to Hourifl again. The cathedral, which colt a long time and a great deal of money in building, is a moll fatly Gothis pile. Its chapter-houfe is particularly admired for its painted glafs, its fine marble falls, its pillars of alabatter, and curious contrivance. In it is the following line in gold letters :

\section*{Ut Rofa, for forum, fie et Domus fla Domorum.}

The choir is remarkable for its fine carvings, particularty the Statues of all the Englifh monarchs; and the windoss are exquifitely painted with the hiflory of the Bible. The lanthorn fteeple is 70 feet fquare, and 188 high, and the windows are 45. At the louth end is a circular light, called the marigold windore from the colour of its glass; and at the north end is a very large one, whole painting reprefents embroidery.

This city is generally reckoned the fecond city in England; but though it flans upon more ground, it is inferior in trade, wealth, and number of people, to Brifol. The inhabitants are reckoned at 16,145 . It is fituated in a fine plain, in the middle of the faure, on both fides the Ouse, walled and divided into four wards, containing 28 parifles. It enjoys large privileges and immunities, conferred upon it by a fucceffion of kings from Henry II. and its chief magiftate has the title of
lord mayor, which is an honour peculiar to it and I. on. don. Richard II. made it a county of itself. The con: fervancy of mot of the rivers of the county, within cen: tain limits, belongs to the lord mayor ard aldermen. The middle archil of the bridge hare over the Oufe is thought to equal the Rialto at Venice in architecture, height, and breadth, the diameter being Si feet, and the height \(5^{5}\). Though this city is 60 miles diftant from the fear, yet flips of 70 tons burden come up the river to it. The town-houfe or guildhall lands upon the bridge, and is fuperior in all respects to that of London. In the Popift times there were nine abbeys here, and a vat number of churches; but of the latter there are only 17 now. The flecple of that of Allhallows is reckoned the fineft in England. The arch. bilhop has a fine palace; and the affembly-room, defigned by the earl of Burlington, is very noble. Here are plays, affemblies, concerts, and the like entertainments, at forme house or other, almoft every night in the week:. In the old cate, built originally by William the Conqueror, and repaired in 1701 , the affizes are kept. It Serves alpo for the county-gaol, which is the neateft and pleafantell in England, with an area larger than that of the King's-bench, and it has a handsome chapel in it, with a good allowance for a preacher. This city has long given the title of duke to tome branch of the royal family.

The plenty and cheapness of provifions induces many perfons of fall fortune, or that would live frugally, to take up their abode here; and the venerable remains of Roman antiquities, and thole of a later date, as abbeys, churches, and caftles, procure this city a wifi from every curious traveller. Many Roman altars, urns, coins, infcriptions, \&c. have been found; and Saxon coins are fill extant that have been flruck here. The members, being two in number, for this city, have precedence of all others, except thofe of London, in the house of commons. An infirmary, after the manner of thole of Bath, Briftol, \&c. hath been erected in it; and a cotton ma. nufacture eftablifined and brought to great perfection. Betides four weekly markets, it has a great many fairs; one, in particular, every other Thursday for cattle and fleet. W. Long. J. r. N. Lat. 53 - 59.

YORKSHIRE, the largelt county of England, bounded on the fouth by Derbyilire, Notinghamihire, and Lincolnftire ; on the north by Durham and Weftmoreland; on the aft by the German ocean; and on the well by Lancahire and a part of Cheflite.-It is upwards of 80 miles in length from eat to weft, nearly as much in breadth, and about 360 in circumference, containing, in the whole, 26 hundreds or wapentakes, 49 market-towns, 563 parihes, 242 vicarages, with many chapels of rate, and 2350 villages. Its area is computed by forme at 4684 square miles, by others at \(3,770,000\) acres, and its inhabitants at \(8,8,892\). It is divided into three parts or riding, viz. the Weft, Eat, and North; fo denominated from their fituation, in reSect of the city of York. Each of there is as large, if not larger, than any ordinary county. These are other divisions, as Richmondthire, Allertonhhire, Howdenfthire, Hallanflire, Craven, Cleveland, Marshland, Holdernefs, \& c .

As the foil and face of the country vary greatly, fo docs the air. In the hilly parts the air is good, tut the foil very indifferent; of the lower forme are mathy, othess drier, and the foil of both rich; but the air of the

\section*{Y O R [ 775 ] Y O R}

York. former is moic foggoy and unhealthy than that of the latter. The manulactures of this county are cutlery and hard-wares; particularly knives, bits, and fpurs; but the principal are flockings and wonllen cloth, with which it fupplies in a great meafure Germany and the North. As to the produce, it abounds in corn, ca'tle, horfes, lcad, and iron, coal, wood, lime, liquorice, alum, jet, \&c. It lies wholly in the northern circuit, and much the greater part of it in the diocefe of York; that only which is called Richmondfoire belonging to the diocefe of Chefler. The members it fends to parliament are \(3 \circ\); of which two are for the ftire and 28 for the towns.

New- \(\mathcal{L}\) ORK, one of the United States of America, is bounded towards the fouth-eall by the Atlantic occan; eait by Connecticut, Miflachufets, and Vermont; north by the \(45^{\text {th }}\) degree of iatitude, which divides it from Canada; northereftwardly by the aiver lroquois or St Lawrence, and the lakes Ontario and Erie; fouthwell and fouth by Penufylvania and Now lerley. The whole flate contains about 44,002 fquare miles, equal to 28,162,050 acres.

The fetllements already made in this flate are chicfly upon two narrow oblongs, extending from the city of New- Iork eaft and north. The one eaft is Longinland, which is 140 miles long, and narrow, and furrounded by the fea. The one extending north is about 40 milcs in breadth, and bifected by Hudion's river.. Aud fuch is the interfestion of the whole tate by the branches of the Hudfon, the Delaware, the Suffrehannah, and other large rivers, that there are few places througlaout its whole extent which are more than 15 or 20 miles from fome navigable ftream. There are few fifh in the rivers, but in the brooks are plenty of trout; and in the lakes yellow perch, fun-fih, falmon-trout, cat-fih, and a vasiety of others.

The State, to fpeak generally, abounds with lakes, fome of falt and others of freh water. It is interfected by ridges of mountains rumning in a north-eaft and fouth-ves direction. Beyond the Allegany mountains, however, the country is a dead level, of a fine rich foil, covered, in its natural ftate, with maple, beach, birch, cherry, black-walnut, locuft, hickory, and Come mulberry trees. On the banks of lake Erie are a few chefnut and oak ridges. Hemlock fwamps are interfperfed thinly through the country. All the creeks that empty into lake Eric have falls, which afford many excelleat mill feats. Eaft of the Allegany mountams, the country is broken into hills with rich intervening valleys. The hills are clothed thick with timber, and when cleared afford fine paflure; the valleys, winen coltivated, produce wheat, hemp, flax, peafe, grafs, oats, frdian corn. Of the commodities prodiced from culture, wheat is the faple; of which immenfe quantities are raifed and exported. Indian corn and peale are likewife raifed for exportation; and rye, oats, barley, \&cc. for home confumption. In fome parts of the State cace!lent dairies are kept, which furrith for the markei but. ter and cheefe.

The fituation of New. York, with refpect ito fore:gn markets, has decidedly the preference to any athe of the United States. It has at all feafons of the year a thort and ealy accefs to the ocean. Its exports to the Weft Indies are, bifcuit, peafe, Indian corn apples, onions, boards, faves, horfes, theep, butter, checee, pict:-
led oyfters, beef, and fork. But wheat is the flaple commodity of the State, of which no lefs than 677,700 buntels were cxported in the year 1775 , befides 2555 tons of bicad and 2823 tons of flour. Infpectore ul flour are appointed to prevent impofition, and to fee that none is exported but that which is deeraed by then merchantable. IBefides the above-mentioned articles, are exported Aax-fced, colton, wool, farfaparilla, coflee, indigo, rice, pig-iron, bar-iron, pot-afld, pearl-aft, furs, deer-fkins, logwood, fuftick, mahogany, tees way, Dil, Madeira wine, rum, tar, pitch, turpentine, whale-fins, fifh, fugars, molafice, falt, tubacco, lard, 8ec. but moft of thete articles are imported for re-expottation. In the ycar 1774, there wesc employed, in the trade of this State, 1075 veflels, whofe tomage amounted to 40,8 t 2.

Since the revolution, the literature of the State has cn . gaged the attention of the legithature. In one of their earlieft feflions an act patfed, conftituling 21 gentlemen (of whom the governor and lieutenant-governor for the time being are mombers (x.0ficiis) a body coporate and politic, by the name and fiyle of "The regents of the univerfity of the State of New-York." They are intrufted with the care of literature in general in the State, and lave power to grant charters of incorporation for erecting colleges ard academies throughout the flate-are to vifit thefe inflitutions as often as they thall think proper, and report their fate to the logifla. ture once a-year. All degrees above that of mafter of arts are to be conferred by the regents. A univerfal toleration is granted in religion.

The fupreme legiflative powers of the State are velled. in two branches, a fenate and affembly. The memlecrs of the fenate are elected by the freeholders of the Statc, who poffefs frechold eflates to the value of :ool. clear of debts. For the purpofe of electing fenators, the Statc is divided into four great difricts, each of which choofes a certain number.

The affembly of the State is compofed of reprefentatives from the feveral counties, chofen amnually in May. Every male inhabitant of full age, who las refided in the flate fix months preceding the day \(0^{\circ}\) cleclion, and poffelfing a freeliold to the value of 201 . in the county where he is to give his vote; or has rented a tencment therein of the yearly value of forty fillings, and has been rated and actually paid taxes-is entitled to rote for reprefertatives in affembly. The number of reprefentatives is limited to 300.

The fupreme executive power of the flate is vofted in a governor chofen once in threc years bs the frcemen of the flate. The lieutenant-governor is, by his office, prefident of the fenate; and, upon an equal diviinon of voices, has a calling vote; but has no voice on other occanions. The governor bas not a feat in the legithatuve; but as a nember of the council of revifion and council co appointment, he has a volt influence in the fiate. The council of resiion is compored of the chancalior, the judges of the fipreme court, or any of thern, and the goremor. In the year 1790 the number of inhabitants in this ftate was 340,120 , of whom 21,324 were negroes; but in 5795 the rrhole norulation of the fate amounted to \(530,17 \%\), making an increate of 190,057 in five years.
Ncw-2ork, a city of North Anerica, capital of the Aate of the fuge name. It is fiwated at the fouth-wer.

\section*{} point of an illand, at the confluence of Hudion and Eaft nivers, and is about four miles in circunterence. '1he filuation is both healthy and pleafant. Surrounded on all fides by water, it is refrethed by cool breezes in fummer, and the air in winter is more temperate than in other places under the fame paraliel. Sork inand is 15 miles in length, and hardly one in breadth. It is joined to the main by a bridge called King's bridgé. The channels between Long and S aten illands, and between Loing and York illands, are fo narrow as to occafion an unulual rapidity of the tides, which is inereafed by the conluence of the waters of Hudfon and Eat sivers. This rapidity, in general, prewents the obliruction of the chamel by ice. There is no baton or bay for the reception of hips; but the road where they lie in Ealt river is defended from the violence of the fea by the iflands which interlock with each otker; fo that, except that of Rhode illand, the harbour of New-York, which admits fluips of any burden, is the beft of the United States. The number of the inhabitants in 1786 was 23,614 .

The molt magnificent edifice in this city is Foderal Hall, at the head of Broad-ftreet; in a gallery in front of which General Wafhington, attended by the fenate and houfe of reprefentatives, took his oath of office at the commencement of the operation of the federal conftitution, 30 th April, 1789 . The other public buildings in the city are, three houles for public worthip for the Dutch Reformed church, four for Prefbytcrians, three for Epifcopalians, two for German Lutherans and Calvinilts, two for Quakers, two for Paptifts, two for Methodifts, one for IMoravians, one for Gatholics, one for French Proteflants, and a Jewifh fynagogue.

King's college was chiefly founded by the voluntary contributions of the inhabitants of the province, aflifled by the general afiembly, and the cornoration of Trinity Church; in the year 1754, a royal charter (and grant of money) being then cbtained, incorporating a number of gentlemen therein mentioned, by the name of " The Governors of the College of the Province of New-York, in the city of New-York, in America;" granting to them the power of conferring all fuch degrecs as are ufually conferred by either of the Englifh univerfities. The building confins of an elcgant flone edifice, three thories high, with four ftair cafes, 12 apartments in each, a chapel, hall, library, mufcum, anatomical theatre, and a fchool for experimental philolophys It is fituated on a dry gravelly foil, about 150 yards from the bank of Hudfon's river, commanding a beautiful and extenfive profpeet. Since the revolution, the legillature paffed an act conftituting \(2 I\) gentlemen (of whom the governor and lieutenani-governor for the time being, are members ex offciis) a body corporate and politic by the name of "The Regents of the Univerfity of the Siate of New-York." They are entrufied with the care of literature in general, and have power to grant charters for erecting colleges and academies through the flate. It is now denominated Columlin college. The ammal revenue arifing from the eftate belonging to the crllege amounts to 1535 . curreney, exclufive of fome bonds which are not as yet productive. It confits of a faculty of arts, and one of plyyfic, the firlt laving a reflent and feven profeflors, and the fecond a dean, and the frme number of profefors. The library and nufeum
were defiroyed during the war, after which h:pward; of 800l. were expended on books to enlarge the library.

The government of this city is at pretent in the hands of a mayor, aldermen, and rummon council, and the city is divided into feven wards, in each o! which an alderman and aftitant are annually chofen \(b_{j}\) the people. A court of fefton is held for the trial of eriminal cau:cs. It is elleemed the molt eligible fituation for commerce in the United Sixies; but the want of grood water is a great inconveniency, there being few wells in the city, and moll of the people are lupplied with frefl water conveyed to their doors in cafks trom the head of Queen fircet. The number of inliabitants in 1796 is fated at more than 33,000 ; and accosding to lome it is fuppofed that they amount at this time to nearly the double. The entries fiom foreign ports in 1795, were 178 hips, 309 brigs, 9 barques, 7 fnons, 268 fchooners, and 170 iloops. Works of defence have been erected to a confiderable extent, and when completed on the oniginal plan, will afford great fecurity to the city. New-York is 95 miles N. E. of Pailadelphia, 197 N. E. of Baltimore, and \(9{ }^{1} 3\) from Charlefton. WV. Long. \(74^{\circ} 9^{\prime} 45^{\prime \prime}\). N. Lat. \(40^{\circ} 42^{\prime}\) \(8^{\prime \prime}\).

YOUNG, Dr EDward, was the fon of a clergyman of the fame name, and was born about the year 1679. When fufficiently qualified, he was matriculated into All-Souls college, Oxford; and defigning to follow the civil law, he took a degree in that profffiton. In this fituation he wrote his foem called The Laf Day, publifhed in 1704 ; which coming from a layman gave univerfal fatisfaction: this was foon after followed by another, entitled 'The Force of hel!gion, or Vanquilhed Love. Thefe productions gained him a refpectable acquaintance; he was intimate with Addifon, and thus became one of the writers of the Spectator: but the turn of his mind leading him to the church, he took orders, was made one of the king's chapiains, and obtained the living of Welwyn in Hartfordhire, worth about 500l. pcr annum, but he never rofe os higher preferment. For fome years before the death of the late prince of Wales, Dr Young atterded his court pretty conftantly ; but upon his deceafe all his hopes of chureh preferment vanilhed; however, upon the death of Dr Hales, he was taken into the fervice of the prin-cefs-dowager of Wales, and fucceeded him as her privy claplain. When pretty far advancer in life, he marsied the lady Elizabeth Lee, daughter of the late earl of Litclfield. This lady was a widow, and bad an amiable fon. and daughter, who both died young. What he felt for their lols, as well as for that of his wife, is finely exprefled in his Night Thoughts, in which the young lady is characterifed under the name of Narcifla; her brother by that of Philander; and his wife, though namelels, is frequently mentioned; and he thus, in an apofrophe to death, deplores the lofs of all the three.

Infatiate areher, could not once fufice !
Thy Thaft flow thrice, and thrice my peace was flin,
And thrice ere thrice yon moon renew'd her horn.
He wrote three tragedies, The lievenge, Bufiris, and The Brothers. Ilis fatites, calleal Love of Fame the univerfal l’aftion, are by many theemed his principal perfornatace; thoggh Swift faid the poct ficuth hate

Young. been either more angry or more merry: they have been characterifed as a flring of epigrams written on one fub. jeet, that tire the reader before he gets through them. His Complaint, or Night Thoughts, exhibit him as a moral and melancholy poet, and are efteemed his maller. piece. They form a fpecies of poetry peculiarly his own, and in which he has been unrivalled by all thofe who attempted to write in this manner. They were written under the recent preflure of his forrow for the lofs of his wife, daughter, and fon-in-law; they are addreffed to Lorenzo, a man of pleafure and the world, and who, as it is infinuated by fome, is his own fon, but then labouring under his father's difpleafure. As a profe-writer, he arraigned the prevailing manners of his time, in a work called The Centaur not Fabuious; and when he was above 80 years of age, publithed Conjectures on Original Compofition. He publifhed fome other pieces; and the whole of his works are collected in 4 and 5 vols 12 mo . Dr Young's turn of mind was naturally folemn ; and he ufually, when at home in the country, fpent many hours of the day walking in his orvn church-yard among the tombs. His converfation, his writings, had all a reference to the life after this; and this turn of difpofition mixed itfelf even with his improvements in gardening. He had, for inft:ace, an alcove with a bencl, fo painted, near his houfe, that at a diftance it looked as a real one which the fpectator was then approaching. Upon coming up near it, however, the deception was perceived, and this motto appeared, Invjifilia non decipiunt, "The things unfeen do not deceive us." Yet, notwithftanding this gloominefs of temper, he was fond of innocent fports and amufement: he inflituted an affembly and a bowlinggreen in the parih of which he was rector, and often promoted the gaiety of the company in perfon. His wit was generally poignant, and ever levelled at thofe who teflified any contempt for decency and religion. His epigram, fpoken extempore on Voltaire, is well known; who happening in his company to ridicule Milton, and the allegorical perfonages of Death and Sin, Young thus addrefled hinn :

One Sunday, preaching in oflice at St James's, he found, that though he frove to make his audience attentive, he could not prevail. Upon which his pity for their folly got the better of all decorums, and he fat back in the pulpit and burll into a tlond of tears. Towards the later part of life he knew his orwn infirmities, and fuffered himfelf to be in pupilage to his boufe-liecper; for he confidered that, at a certain time of life, the fecond childhood of age demanded its wonted protecition. His fort, whofe boyifl follies were long obnoxious to paternal feverily, was at lafl forgiven in lis will ; and our poet died regretted by all, having performed all that man could do to fill his poft with dignity. His deads happencd'in 5765 .

YOU'LI, that fate of man in which he approaches towards his greated perfection of body.

YPRLS, a handfome, large, and populous town of the Aufrian Netherlands, with a Lifhop's fee. It has a confiderable manufactory in cloth and ferges, and every year in Lent there is a confiderable fair. It is one of the barrier towns, but was befieged and taken by the French in 1744, and alfo in 179.4. It is feated in a fertile plain on the river Y'pre, in E. Long. 2. \(4^{8 .}\) N. Lat. 50.51.

YTTKIA, one of the lately difcovered earths. For an account of its properties and combinations fee CHEMISTRY, \(\mathrm{N}^{\circ}{ }^{1} 457\).

Titrio-Tantafite, a mineral fubflance containing the new earth yttria, and the new metal tantalium, which latter is found by Dr Wollafton to be identical with columbium.

YUCCA, Adam's Needle, a genus of plants of the clafs hexandria. The fecies of this plant are all exceedingly curious in their growth, and are therefore much cultivated in gardens. The Indians make a k.und of bread from the roots of this plant.

YULE, Yool, or Iul. See Iul.
YUNX, a genus of birds of the order pica. See Ornthology Index.
2. 2 , or 2 , the \(24^{\text {th }}\) and laft letter, and the 19 th confo2. nant of our alphabet; the found of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a fhutting and opening of the teeth at the fame time. This letter has been reputed a double confonant, having the found \(d s\); but fome think with very little reafon: and, as if we thought otherwife, we often double it, as in puzz/e, muzzle, \&c. Among the ancients, \(Z\) was a numeral letter, fignifying 2000 ; and with a dafh added a-top, \(\overline{\mathrm{z}}\) fignified 2000 times 2000 , or \(4,000,000\).

In abbreviations this letter formerly flood as a mark for feveral forts of weights; fometimes it fignified an ounce and a half; and very frequently it food for half

VoL. XX. Part II.
an ounce; fometimes for the cighth part of an ounce, or a dram troy weight; and it has in earlier times been ufed to exprefs the third part of an ounce or eight feru.ples. ZZ were ufed by fome of the ancient phyficians to exprefs myrrh, and at prefent they are often ufed to fignify zinziber or ginger.

ZAARA, Zapara, Sahara, or the Defert, a vaft country of Africa. bounded on the north by Barbary, on the eaft by Fezzan and Caflina, on the fonth by Tombuctoo, and on the weft by the Atlantic ocean. Zaara contains a variety of wandering nations, all proceeding from Arabs, Moors, and fugitive Portuguefe, who took refuge therc when the family of the Sherifs made themfelves mafters of the three kingdoms of Bar5E
bary.

Zaara bary. All thefe people bear indifcriminately the names of Nars, Moors, or Arabs. They are fubdivided into various nations, of which the moft confiderable are the

Mongearts, Trafars, and Bracnars. The Mongearts lead a wandering life, and live chiefly on the milk of their flocks, with a little barley-meal, and fome dates. The poorer fort go naked, except the females, who commonly wrap a clout about their middle, and wear a kind of bonnet on their head; but the wealthier fort have a kind of loofe gown, made of blue calico, with large fleeves, that is brought them from Negroland. When they move from one place to another for frefh paflure, water, or prey, moft of them ride on camels, which have generally a fort of faddle betwcen the buncli and the neck, with a fring or Atrap run through their noftrils, which ferves for a bridle; and inftead of fpurs they ufe a fharp bodkin. Their tents or huts are covered with a coarfe fluff, made of camel's hair, and a kind of wool or mofs that grows on the palm trees. Thefe Arabs live here under the government of their theiks or cheyks; as in Arabia, Egypt, and other places. The other two tribes are rather more civilized. They are all Mahometans.

ZABULON, in Ancient Geography, one of the twelve tribes; bounded on the north by the tribes of Afher and Naphthali ; on the eaft by the fea of Galilee; on the fouth by the tribe of Iflachar or the brook Cifon, which ran between both; on the weft by the Mediterranean; fo that it touched two feas, or was bimarnus.

Zabulon, in Ancient Geography, a very frong town in the tribe of that name, on the Mediterranean, firnamed of men, near Ptolemais: its vicinity to which makes it probable that it was alfo Chabulon, unlefs either name is a faulty reading in Jofephus; diftant abous 60 fladia from Ptolemais.

ZACYNTHUS, in Ancient Geography, an ifland to the fouth of Cephalenia 60 ffadia, but nearer to Peloponnefus, in the Ionian fea, furmerly fubject to Ulyffes, in compafs above 160 ftadia, woody and fruitful, with a confiderable cognominal town and a port. The ifland lies over againgt Elis, having a colony of Achreans from Peloponnefus, over againt the Corinthian gulf. Both ifland and town are now called Zante.

ZAFFRE, is the oxide of cobalt, employed for painting pottery ware and porcelain of a blue colour. The method of preparing it is as follows: The cobalt taken out of the mine is broken with hammers into pieces about the fize of a hen's egg; and the fony involucrum, with fuch other heterogeneous matters as are diftinguilhable by the eye, are feparated as much as poffible. The chofen mineral is then pounded in flamping mills, and fifted through brafs wire fieves. The lighter parts are wafled off by water, and it is afterwards put into a large flat-bottomed arched furnace, refembling a baking oven, where the flame of the wood reverberates upon the ore; which is occafionally ftirred and turned with long handled iron hooks or rakes; and the procefs is continued till it ceafes to emit any fumes. The oven or furnace is terminated by a long horizontal gallery, which ferves for a chimney; in which the arfenic, naturally mixed with the ore, fublimes. If the ore contains a little bifmuth, as this femimetal is very fufille, it is collected at the bottom of the furnace. Ithe cobalt remains in the flate of a dark gray oxide,
and is called zaffre. One hundred pounds of the cobalt ore lofe 20 and even 30 per cent. during this operation, which is continued 4 or even 9 hours, according to the quality of the ore. The roalled ore being taken out from the furnace, fuch parts as are concreted into lumps are pounded and fifted afrelh. Zafire, in commerce, is never pure, being mixed with two or rather three parts of powdered flints. A proper quantity of the beft fort of thefe, after being ignited in a furnace, is thrown into water to render it friable, and more eafily reduced to powder; which, being fifted, is mixed with the zafire, according to the before-mentioned dofe; and the mixture is put into cafks, after being moiltened with water. This oxide, fufed with three parts of fand and one of potalli, forms a blue glafs; which, when pounded, fifted, and afterwards ground in mills, included in large caiks, forms fimalt.

The blue of zaffre is the moft folid and fixed of all the colours that can be employed in vitrification. It fuffers no change from the mof violent fire. It is fuccefsfully employed to give haades of blue to enamels, and to the cryftal-glaffes made in imitation of fome opaque and tranfparent precions fones, as the lapis lazuli, the turquois, the fapphire, and others of this kind.

ZALEUCUS, a famous legillator of the Locrians, and the difciple of Pythagoras, flourifhed 500 years B. C. He made a law, by which he punifhed adulterers with the lofs of both their eyes; and his fon offending, was not abfolved from this punifhment: yet, to frow the father as well as the jult lawgiver, he put out his own right, and his fon's left eye. This example of juftice and feverity made fo ftrong an impreffion on the minds of his fubjects, that no inflance was found of the commiffion of that vice during the reign of that legintator. It is added, that Zaleucus forbade any wine being given to the fick on pain of death, unlefs it was prefcribed by the phyficians; and that he was fo jealous of his laws, that he ordered, that whoever was defirous of changing them, ftould be obliged, when he made the propofal, to have a cord about his neck, in order that he might be immediately frangled, if thofe alterations were efteemed no better than the laws already eftablifhed. Diodorus Siculus attributes the fame thing to Charondas legiflator of the Sybarites.

ZAMA, in Ancient Geography, a town of Chamane, a diftrict of Cappadocia, of unknown fituation.-Another Zama, of Mefopotamia, on the Saocoras, to the fouth of Nifibis.-A third, of Numidia, diflant five days journey to the weft of Carthage: it was the other royal refidence of the kings of Numidia, hence called Zama Regia. It flood in a plain; was fronger by art than nature ; richly fupplied with every neceflary ; and abounding in men, and cvery weapon both of defence and annoyance.

The laft of thefe is remarkable for the decifive battle fought between the two greateft commanders in the world, Hannibal the Carthaginian and Scipio Africanus. Of this engagement, the moft important perhaps that ever was fought, Mr Hooke gives the following account.
"Scipio drew up his army after the Roman manner, except that he placed the cohorts of the Principes direally behind thofe of the Haflati, fo as to leave fufficient fyace for the enemy's eleghants to pafs through

\section*{Z A M}

Zama.

\section*{\(\underbrace{\text { Znan. }}\)} from front to rear. C. Lerlius was pofted on the left wing with the Italian horie, and Mafiniffa with his Numidians on the right. The intervals of the firit line Scipio filled up with his Velites, or light-armed troops, ordering them, upon a fignal given, to begin the batthe; and in cafe they were repulfed, or broke by the elephants, to run back through the lanes before mentioned, and continue on their hight till they were got behind the Triarii. Thafe that were wounded, or in danger of being overtaken, were to turn off to the right and left through the faces between the lines, and that way efcape to the rear.
"The army thus drawn up, Scipio went from rank to rank, urging his foldiers to confider the confequences of a defeat and ihe rewards of victory: on the one hand, certain death or llavery (for they liad no town in Africa flong enough to protect them); on the other, not only a lafting fuperiority over Carthage, but the empire of the reft of the world.
"Hannibal ranged all his elephants, to the number of above 80 , in one front. Behind thele he placed his mercenaries, confifting of 12,000 men, Ligurians, Gauls, Baleares, and Mauritanians.
"The new levies of Carthaginians and other Africans, together with 4000 Macedonians, under a general named Sopater, compofed the fecond line. And in the rear of all, at the diffance of about a furlong, he pofted his Italian troops, in whom he chiefly confided. The Crthaginian horfe formed his right wing, the Numidians his left.
" He ordered their feveral leaders to exhort their troops not to be difcouraged by their own weaknefs, but to place the hope of victory in him and his Italian army ; and particularly directed the captains of the Carthaginians to reprefent to them what would be the fate of their wives and children if the event of this battle fhould not prove fuccefsful. The general himfelf, walking through the ranks of his Italian troops, called upon them to be mindful of the 17 campaigns in which they had been fellow-foldiers with him ; and of that conflant feries of victories by which they had extinguinhed in the Romans all hope of ever being conquerors. He urged them to remember, above all, the battles of Trebia, Thrafymenus, and Canne; with any of which the approaching battle was in no wife to be compared, either with refpect to the bravery or the number of the enemy.
- The Romans were yet unfoiled, and in the height of their frength, when you firf met them in the field; neverthelefs you vanquiflied them. The foldiers now before us are either the children of the vanquifhed, or the remains of thofe whom you have often put to flight in Italy. Maintain therefore your general's glory and your own, and eftablifh to yourfelves the name of invincible, by which you are becorne famous throughout the world.'
"When the Numidians of the two armies lad \(\mathbb{E k i r}\) mifhed a while, Hannibal ordered the managers of the elephants to drive them upon the enemy. Some of the bealts, frightened at the noife of the trumpets and other inflruments of war which founded on all fides, immediately ran back among? the Numidians of the Carthaginian left wing, and put them into confufion; which Mafinilfa taking advantage of, entirely routed them. Great deftruction was made of the Velites by the reft of the elephants, till thefe allo being terrified, fome of
them ran through the void fpaces of the lloman army which Scipio had left for that purpofe; others falling in among the cavalry of the enemy's riglit wing, gave Lelius the fame opportunity against the Carthaginian horfe as had been given to Matiniffe againt the Numidian, and of which the LRoman did not fail to make the fame ule. After this the infantry of the foremof lines joined battle. Hannibal's mercenaries had the advarl= tage in the begiming of the conflet ; but the Roman Haftati, followed and encouraged by the Irincipes, who exhorted them to fight manfully, and thowed thenfelves ready to aflif them, bravely luftained the attack, and at length gained ground upon the enemy. 'Ihe mercenarics not leeing feafonably fupported by their fecond line, and therelose thinking themfelves betraycd, they in their retreat fell furiounly upon the Alricans; fo that thefe, the Hattati coming up, were obliged to fight for fome time both againg their own mercenaries and the enemy. When the two Carthaginian lines had ceafed their mutual rage, they joined their ftrength; and though now but a mere throng of men, broke the Haflati: but then the Principes advancing to the aflutance of the latter, rellored the battle; and moft of the Africans and mercenaries were here cut off. Hamibal did not advance to their relief, the Roman Triarii not having yet engaged, and the Principes being fill in good order ; and left the routed Africans and mercenaries hoould break the ranks of his Italian foldiers, he commanded thefe to prefent their fpears at thofe who fled to thein for protection, which obliged the runaways to move off to the right and left.
"The ground over which the Romans mut march before they could attack Hannibal being ftrewed with heaps of dead bodies and weapons, and being lippery with blood, Scipiofeared that the order of his battalions would be broke, fhould he pafs it haftily. To avoid this mifchief, he commanded the Haftati to give over the purfuit, and halt where they were, oppofite to the encmy's centre : after which, having fent all his wounded to the rear, he advanced leifurely with the Principes and Triarii, and placed them on the wings of the Haflati. Then followed a flarp engagement, in which victory was long and eagerly difputed. It would feem that the Romans, though fuperior in number, were once upon the point of lofing the day; for Polybius tells us, that Mafinifia and Lælius came very feafonably, and as if fent from hearen, to their affiftance. Thefe generals being returned from the purfuit of the cavalry, fell fuddenly upon the rear of Hannibal's men, mon of whom were cut off in their ranks; and of thofe that fled, very few efcaped the horfe, the country all around being a plain.
"There died of the Carthaginians in the fight above 20,000 , and almont the like number were taken prifoners. The lofs on the fide of the Romans amounted to about 2000 men. Hannibal efcaped with a few horfe to Adrumetum, having performed every thing in the engagement which could be expected from a great general. His army (fays Polyhius) could not have been more Akilfully drawn up. For as the order of the Roman battalions makes it extremely difficult to break them, the Carthaginian wifcly placed his elephants in the front, that they might put the enemy in confufion before the armies thould engage. In his firt line he placed the mercenaries; men bold and active, but not

\section*{Z A P [780] Z E A}
well difciplined, that by their impetuofity he might give a check to the ardour of the Romans. The Africans and Carthaginians, wlofe courage he doubted, he polted in the middle between the mercenarics and his Italian foldiers, that they might be forced to fight, or at leaft that the Romans, by llaughtering them, might fatigue themfelves and blunt their weapons. Laft of all, lue drew up the troops he had difciplined himfelf, and in whom he chiefly confided, at a good dittance from the fecond line, that they might not be broken by the route of the Africans and mercenaries, and kept them in referve for a vigorous attack upon a tired and weakened enemy."

ZANGUEBAR, a country in Africa, lying on the eaftern coalt, between three degrees of north latitude, and 18 fouth. It includes feveral petty kingdoms, in which the Portuguefe have various fettlements. The inhabitants, except thofe converted by the Portuguefe, are all Mahometans or idolaters; and the latter much the more numerous. The names of the pincipal territories are Mombaza, Lamon, Melinda, פuiola, and Mofambique. The Portuguefe have built feveral forts in Mombaza and Mofambique, and have fettled feveral colonies there. They trade with the negroes for flaves, ivory, gold, oftrich-feathers, wax, and drugs. The productions are much the fame as in other parts of Africa between the tropics.

ZANONIA, a genus of plants of the clafs pentandria. See Botiny Index:

ZANTE, an illand of the Mediterranean, near the coaft of the Morea, 19 miles fouth-ealt of the inland of Cephalonia, belonging to the Venetians. It is about 24 miles in length and 12 in breadth, and very pleafant and fertile; but its principal riches confift in currants, with which it greatly abounds. They are cultivated in a very large plain, under the Thelter of mountains on the fhore of this illand; for which reafon the fun has greater power to bring them to perfect maturity. The town called Zante may contain near 20,000 inhabitants; the whole illand contains about 40,000 . The houles are low, on account of the frequent earthquakes, for fcarce a year paffes without one; however, they do no great damage. The natives §peak both Greek and Italian. There are very few Roman Catholics amongg them; but they have a bilhop as well as the Greeks. This place has no fortifications, but there is a fortrefs upon an eminence planted with cannon. In one part of this inland is a place which thakes when trod upon like a quagmire; and a fpring which throws out a great eical of bitumen, efpecially at the time of an earthqualse. It ferves inftead of pitch to pay the bottoms of the hips, and about 100 barrels in a year are ufed for this purpofe. There are about 50 villages in the illand; but n:o other large town tefide Zante. It is feated on the eattern fide of the illand, and has a good harbour. The Englith and Dutch have cacla a faclory and conful here. E.. I.ong. 21. 3. N. I.at. 37. 53.

ZAN CHOXYLUM, the Toothache-tree, a genus of plants of the clafs of diœcia; and in the natural fyftem arranged under the 46 th order, Hederacere. See Botasy Index.

ZAPAl'A, a kind of feaft or ceremony held in Italy in the courts of certain princes, on St Nicholas's day; wherein people hide prefents in the thoes or dippers of thofe they would do honour to, in fuch a manner
as may furprife them on the morrow when they come \(Z_{\text {apata, }}\) to drefs; being done in imitation of the practice of St Nicholas, who ufed in the night-time to throw purfes of money in at the windows to marry poor maids withal.

ZEA, Indian Corn ; a genus of plants of the clafs monocia. See Botany Index.-There is only one fpe. cies, the Mays, maize. The Indians in New England, and many other parts of America, had no other vege. table but maize or Indian corn for making their bread, They call it zucachin; and in the United States of \(\Lambda\) merica there is much of the bread of the country made: of this grain, not of the European corn. In Italy and Germany alfo there is a fpecies of maize which is the food of the poor inhabitants.

The ear of the maize yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grain is the ear, often more, if the ground be goud. Each of thefe rows contains at leaft 30 grains, and each of thefe gives much more flour than a grain of any of our corn. The grains are ufually cither white or yellowih; but fometimes they are red, bluifh, greenifts, or olive-coloured, and fometimes Atriped and variegated. This fort of grain, though fo effentially neceffary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; fo that the rains often fall heavy upon it while on the flaik, and the birds in general peck it when it is foft and unsipe. Nature has, to defend it from thele accidents, covered it with a thick hulk, which keeps off flight rains very well: but the birds, if not frighted away, often eat through it, and devour a great quantity of the grain.

There are three or four varieties of maize in different parts of America. That of Virginia is very tall and robuft, growing to feven or eight feet high; that of New England is fhorter and lower. And the Indians farther up in the country have a yet fmaller kind in common ufe. The lalk of the maize is jointed like the fugar-cane ; it is very foft and juicy, and the juice is fo fweet and faccharine, that a fyrup, as fweet as that of fugar, has been often made of it; and things fweetened with it have been found not diftinguiftable from thofe done with fugar. It has not been tried yet whether it will cryftallize into fugar; but in all probability it will.

The Americans plant this corn any time from the beginning of March to the beginning of June; but the beft feafon is the middle of April. The favage Indians, who knew nothing of our account of months, ufed to guide themfelves in the feed-time of this ufeful plant by the budding of come particular trees of that country, and by the coming up of a fort of fifh into their rivers which they call the aloofe. Thefe things were both fo segular, that they were in no danger of miftaking the time.

The manner of planting maize is in rows, at equal difances, every way about five or fix fect. They open the earth with a hoe, taking away the furface to three or four inches deep, and of the breadth of the hoc; they then throw in a little of the finer earth, fo as to leave the hoe four inches deep or thereabouts, and in each of thefe holes they place four or five grains at a little diffance from one another. If two or three of thefe grow up, it is very well; fome of them are ufually deftroyed either by the bids or other animals.

\section*{Z E A}

When the young plants appear, they hoe up the weeds from time to time; and when the flalk gathers fome ftiength, they raife the earth a little about it, and continue this at every hoeing till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the fize of a hop-hill, and after this they leave it till the time of harveft, without any farther care. When they gather the ears, they either immediately frip off the corn, or elfe hang up the ears, tied in traces at diftances from one another; for if they are laid near together, they will heat and rot or elfe fprout and grow ; but kept cool and feparate, they will remain good all the winier. The bert method is to thrafh out the corn as foon as the harveft is over, to dry it well on mats in the fun, and then lay it up in holes of the ground, well lined with mats, grafs, or the like, and afterwards covered at top with more earth. The moft careful among the Indians ufe this method, and this fort of fubterranean granary always proves good.

The ufes of this plant anong the Indians are very many. The great article is the making their bread of it ; but befides this, the flalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they ufually leave them on the ground for the cattle to feed on. The huiks about the ear are ufually feparated from the refl, and make a particular fort of fodder, not inferior to our hay. The Indian women have a way of flitting them into narrow parts, and they then weave them artificially into balkets and many other toys. The original way of eating the grain among the Indians was this: they boiled it whole in water till it fiwelled and became tender, and then they fed on it either alone or ate it with their filh and venifon inftead of bread. After this, they found the way of boiling it into a fort of pudding, after bruifing it in a mortar; but the way of reducing it to flour is the beft of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars and fifting it. This flour they lay up in bags as their conftant provifion, and take it out with them when they go to war, eating it either dry or with water. The Englifh have contrived, by mixing it into a ftiff parte, either by itfelf or with rye or wheat-meal, fermenting it with leaven or yeafl, and baking it in a hot oven, to make good bread of it. They have likewife found out a method of making good beer, either of the bread or by malting the grain.

ZEAL, paffionate ardour for any perfon or caufe. It is moft frequently ufed to denote a ffrong and warm attachment to the diftinguifhing doctrines or worfhip of fome particular fect of Chrifians. Thus we fay, a zealous Catuinif, Aiminian, or Papif; though we may likewife with the greateft propriety fay of an uprigl:t and benevolent man, that he is zealous of. good works.

ZEALAND, the chief of the Danill iflands, is fituated at the entrance of the Baltic fea, bounded by the Schaggerrac fea on the north; by the Sound, which fcparates it from Schonen, on the eaft; by the Baltic fea on the fouth; and by the flrait called the Great Bett, which feparates it from the ifland of Funen, on the weft; being of a round figure, near 200 miles in circumference: the chief town is Copenhagen.

Zealand, is alfo a province of the United Netherlands, confifting of eight iflands, whicl: lie in the mouth of the river Scheldt, bounded by the province of Hol-
land, from which they are feparated by a narrow chan. nel on the north ; by Brabant on the eall ; by Flanders, from which they are feparated by one of the branches of the Scheldt, on the fouth; and by the German ocean on the weff.

Now ZEAI.AND, a country of Afia, in the South Pacific ocean, firt dilcovered by Tafman, the Dutch navigator, in the year 1642 , who gave it the name of Siaten Land, though it has been generally dillinguifhed in our maps and charts by the name of New Zenland, and was fuppofed to be part of a fouthern continent: but it is now known, from the late difcoveries of Captain Cook who faited round it, to confift of two large inlands, divided from each other by a ftrail four or five leagues broad. They are fituated between the latitudes of 34 and 48 degrees fouth, and between the lnggitudes of 166 and 180 degrees ealt from Greenwich. One ot thele illands is for the moft part mountainous, rather barren, and but thinly inhabited; but the other is much more fertile, and of a better appearance. In the opinion of Sir Jofeph Banks and Dr Solander, cvery kind of European fruits, grain, and plants, would Hourihs here in the utmoll luxuriance. From the vegetables found here, it is fuppofed that the winters are milder than thofe in England, and the fummers not hotter, though more equally warm; fo that it is imagined, that if this conntry were fettled by people from Europe, they would, with moderate induliry, be foon fupplied, not only with the ncceffaries, but the luxuries of life, in great abundance. Here are forefts of vaft extent, filled with very large timber trees; and near 400 plants we:e found here that had not beerr defcribed by the naturalifts. The inhabitants of New Zealand are flout and robuft, and equal in flature to the largeft Europeans: Their colour in general is brown, but in few deeper than that of the Spaniard who has been expofed to the fun, and in many not fo deep; and both fexes have good features. Their drefs is very uncouth, and they mark their bodies in a manner fimilar to the inhabitants of O taheite, and which is called tattowing. Their principal neapons are lances, darts, and a kind of battleaxes; and they have generally flown themfelves very hoftile to the Europeans who have vifited them.

ZEALOTS, an ancient feat of the Jews, fo called from their pretended zeal for God's lay and the honour of religion.
ZEBRA. See Equus, Mammalia inder.
ZEBU, a name given by M. de Buffon to the bos indicus of Linmens. See Mamalia Ifdex:

ZECHARIAH, a canonical book of the Old Tefta. ment. See Scripture, No 80.
ZECHIN, or Zecchiso. See Sequin.
Zedoary, in the Materia Medica. See Krempferta.
ZELL, a city of Germany in the circle of Lower Saxony, capital of the duchies of Zell and Lumenburg, fituated at the confluence of the rivers Aller and Fuhle, 30 miles north of Hanovir, and 40 fouth of Lunenburg. E. Long. 10. 12. N. Lat. 52.49.

ZEMBI.A, Nova, a very large ifland, lying in the Northern ocean, to the north of Ruffia, from which it is feparated by the itrait of Waigate. It has no inhabi: tants except wild beafts, particularly white foxes and bears. In 1595 a Dutch velfel was caft away on the coalt, and the hip's company were obliged to winter

Zemindar. here ; but they did not fee the fun from the fuurth of November to the beginning of February, and had great difficulty to kecp themfelves from being frozen to death.

ZEMINDAR, in its original meaning, fignifies a great landholder of Bengal; but it is now more Arichly applicable to thofe who have their title conflituted or confirmed by a patent or charter from government, by which they hold their lands or zemindaries upon certain conditions. It appears from hiftory, that, in times prior to the irruption of the Mahomedans, the rajahs who held their refidence at Delhy, and poffefied the fovereignty of Hindoftan, deputed officers to colle et their revenues. The word aemindar is Perlian, and that language can have had no currency in the countries of India, until it was introduced by the people of Perfia. When the emperor Shehab-ul-Dien Ghory conquered the empire of Hindoftan at the end of the 12 th century, he left Sultan Cutub-ul-Dien to be his viceroy at Delhy, and adminifter the government of Hindoftan. From that time the cuftoms and praclices of the Mahomedans began gradually to be eftablithed in India: their armies were fent into the countrics of the seduced rajahs, under the command of omrahs, in order to preferve the conquelt ; and lands were allotted to them to defray the exponce. From hence arofe the fyltem of Jaghiredarry in Hindoftan. But when thefe Omrah Jaghiredars had eftablifhed their own ftrength, feveral of them rebelled againt the imperial authority, and afpired at the crown. Thus circumftanced, the emperors, in order to obviate thefe mifchicfs, thought it would be more politic to commit the management of the country to the native Hindoos, who had moft diftinguifhed themfelves by the readinefs and conftancy of their obedience to the fovereign power.

In purfuance of this plan, diftricts were allotted to numbers of them under a reafonable revenue (Jummah Monâfib), which they were required to pay in money to the governors of the provinces, deputed from the emperor. And in cafe any one of the omrahs or provincial governors fhould fwerve from his allegiance, the zemindars of that country were 20 exert themfelves in fuch a manner as thould check rebellion, and reflore good government. For this purpofe, grants of zemindary were feverally conferred upon fuch of the Hindoos as were obedient; defcribing their apportionment of the country; and every perfon who had received a grant under the authority of the crown was thereby fully invefted with the functions of zemindar.

The functions of a zemindar are, ift, The prefervation and defence of their refpective boundaries from traitors and infurgents. 2dly, The tranquillity of the fubjects, the abundance of cultivators, and increafe of his revenue. 3 dly , The punifhment of thieves and robbers, the prevention of crimes, and the deftruction of highwaymen. The accomplifhment of thefe objects is confidered in the royal grant as the difcharge of office to the fovereign; and on that account the word office (khidmut) is employed in the Dewanny Sunnud for a zemindary.

It was a rule in the times of the ancient emperors, that when any of the zemindars died, their effects and property were fequefrated by the government. After which, in confideration of the rights of long fervice, which is incumbent on fovereigns, and elevates the dig-
nity of the employer, funnuds for the office of zemin. Zemindar, dary were granted to the childien of the deceafed ze. Kend. mindar; and no other perfon was acctpted, becaufe the inhabitants could never feel for any franger the attachment and affection which they naturally entertain for the family of their zemindar, and would have been afflicted if any other had been put over them. For this realon, the emperors, confidering it as a means of conciliating the minds of the people, gracioully fixed and confirmed the childien of the deceated zemindar in the office of their fathers and grandfathers, by ifluing new funnuds to transfer the poficfion to them. By degrees zemindarics became truly heritable property, which, however, could be transferred by gift or lale from one family to another. They could likewife be forfeited to the fovereign, by the zemindar's deviating from his al. legiance, neglecting to pay his tribute, or to difcharge the duties of his Itation.

It is univerfally known, fays Sir Charles Roufe Boughton, that, when the three provinces of Bengal, Bahar, and Oriffa, were ceded to the Britih Eaft India Company, the country was diftributed among the zemindars and talookdars or holders of land, who paid a ftipulated revenue, by twelve inflalments, to the fovereign power or its delegates. They affembled at the capital in the beginning of every Bengal year (commencing in April), in order to complete their final payments, and make up their annual accounts; to fetle the difcount to be charged upon their feveral remittances in various coins for the purpofe of reducing them to one ftandard, or adjuft their concerns with their bankers; to petition for remiffions on account of florms, drought, inundation, difturbances, and fuch like; to make their reprefentations of the ftate and occurrences of their diffricts: after all which they entered upon the collections of the new year ; of which, however, they were not permitted to begin receiving the rents from their own farmers, till they had completely clofed the accounts of the preceding year, fo that they might not en. croach upon the new rents, to make up the deficiency of the pall. Our author proves, we think completely, the right of the zemindars to transfer their poffections, either by inheritance to their children, or, with the confent of the fovereign, to other families; and he argues Atrenuoufly and fucceffully againt the bad policy, as well as injuftice, of interfering with thofe rights, as long as the zemindars difcharge the duties of their feveral ftations.

ZEND, or Zendavesta, a book afcribed to Zoroafter, and containing his pretonded revelations; which the ancient Magicians and modern Perfees, called alfo Gaurs, obferve and reverence in the fame manner as the Chriffians do the Bible, and the Mahometans the Koran, making it the fole rule both of their faith and manners. The word, it is faid, originally fignifies any inftrument for kindling fire, and is applied to this book to denote its aptitude for kindling the dlame of religion in the hearts of thofe who read it.

The Zend contains a reformed fyflem of Magianifm; teaching that there is a Suprcme Being, eternal, felf-exiftent, and independent, who created both light and darknefs, out of which he made all other things; that there are in a ftate of conflict, which will continue till the end of the world ; that then there flaall be a general refurrection and judgement; and that juft retribution

\section*{Z E N [ 783 ] Z E N}

Zend fhall be rendered unto men according to their worlis; that the angel of darknefs with his followers fhall be configned to a place of everlatling darknefs and punifhment, and the angel of light with his difciples introdu. ced into a ftate of everlafting light and happinefs; after which light and darknels fhall 110 more interfere with each other. The Zend alfo enjoins the cunftant maintenance of facred lires and fire temples for religious worthip; the diltinction of clean and unclèan beafts; the payment of tithes to priefts, which are to be of one family or tribe; a multitude of wallings and purifications, refembling thofe of the Jewilh law; and a variety of rules and exhortations for the exercife of benevalence and charity.

In this book there are many panages evidently taken out of the Scriptures of the Old Teftament, particularly out of the Pfalnos of David: The author reprcfents Adam and Eve as the firt parents of all mankind, gives in fubltance the fame account of the creation and deluge with Mofes, differing indeed with regard to the former, by converting the fix days of the Mofaic account into fix times, comprehending in the whole 365 days; and fpeaks alfo of Abraham, Joleph, Mofes, and Solomon. Moreover, Dr Baumgarten afferts, that this work contains doctrines, opinions, and facts, aftually borrowed from the Jews, Chritians, and Mahometans; whence, and from other circumftances, he concludes that both the hiltory and writings of this prophet were probably invented in the later ages, when the fire-worthippers under the Mahometan government thought fit to vindicate their religion from the fufpicion of idolatry.

At whatever period the Zend may have been written, we are affured by Dr Hyde, that it is in the pure old Peifian language, and in the character called Peplavi. Some parts of it contain the original next, and others Zoroafter's fecond thoughts fubjoined, for explailing more fully his doctrine. Thefe were occafioned by the oppofition of adverfaries, and unforefeen circumftances which occurred during the fabrication of the impolture. About 300 years ago, when the old Perfian language had become antiquated and little underftood, one of the deftours or high-priefts among the Perfees compoled the Sadda, which is a compendium in the vulgar or modern Perfic tonguc, of thofe parts of the Zend that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroafter, ferving as an authoritative rule of faith and practice for his fullowers. This Sadda is written in a low kind of Perfic verfe, and as Dr Hyde informs us, it is bonorum et malorum farrago, having many good and pious things, and others very fuperffitious and trifling. See Persees and ZoroASTER.

ZENITH, in Afronomy, the vertical point, or a point in the heavens directly over our heads.

ZENO Eleates, an eminent Grecian philofopher,

Enfold \({ }^{*}\) s
Hiflory of Fibito \({ }^{2}\) tbj. was born at Elea about \(50+4\) years before Chrif. He was a zealous friend of civil liberty, and is celebrated for his courageous and fuccefsfu] oppofition to tyrants; but the inconfitency of the ftories related by different writers concerning him in a great meafure deftroys their credit. He chofe to refide in his fmall native city of Elea rather than at Athens, becaufe it afforded freel fcope to his independent and generous firit, which could rot eafily fubmit to the reftraints of authority. It is related, that he vindicated the warmth with which be re-
fented reproach, by faying, "If I wese indifferent to cenfure, I thould alto be indifferent to praife." The invention of the dialectic art has been improperly aferibed to Zeno; but there can be no doubt that this philofopher, and other metaphyfical difputants in the Eleatic lect, employed much ingenuity and fubtlety in exhibieing examples of moft of the lagical arts, which were aficrwards reduced to rule by Arillotle and others.

According to Arifotle, he taught, that nothing can be produced either from that which is fimilar or collimio lar; that there is only one being, God ; who is eternal, homogencous, and ipherical, neither finite nos indinite, neithor quiefcent nor moveable; that there are many worlds; that there is in nature no racuum; that all bodies are compoled of four elements, heat and moifture, cold and drynels; and that the body of man is from the carth, and his foul an equal misture of the fe four elements. He argued with great fubtlety againft the polfibility of motion. If Seneca's account of this philofopher deferves credit, he rcaclied the highert point of fcepticifm, and denied the real exiftence of external ob. jects. The truth is, that after all that has been advanced by different writers, it is impoffible to determine whether Zeno underfood the term one, metaphyfically, logically, or phyfically ; or whether he admitted or denied a nature properly divine.

Zeno, the founder of the feet of the Stoics, was bom about 300 years before Chrift at Citjum, in the illand of Cyprus. This place having been originally peopled by a colony of Phœenicians, Zeno is fometimes called a Pho. nician. His father was by profeffion a merchant, but difcovering in the youth a flrong propenfity towards learning, he early devoted him to philofophy. In his mercantile capacity he had frequent occafion to vifit Athens, where he purchafed for his fon feveral of the writings of the molt eminent Socratic philofophers. Thefe he read with great avidity; and when he was about \(\mathrm{g}^{\circ}\) years of age, he detcrmined to take a voyage to a city which was fo celebrated both as a mart of trade and of fcience. If it be true, as fome writers relate, that be brought with him a valuable cargo of Phoenician purple, which was loft by flipwreck upon the coaft of Piraus, this circumftance will account for the facility with which he at firt attached himfelf to a lect whofe leading principle was the contempt of riches. Upon his firt arrival in Athens, going accidentally into the hop of a bookfellers, he took up a volume of the Commentaries of Xenophon; and after reading a few paffages, was fo much delighted with the work, and formed fo high an idea of the author, that he alked the bookfeller where he might meet with fuch men. Crates the Cynic philofopher happening at that inftant to be pafling by, the bookfeller pointed to him, and faid, "Follow that man." Zeno attended upon the inftructions of Crates, and was fo well pleafed with his doctrine that he became one of his difciples. But though he admired the general principles of the Cynic fchool, he could not eafily reconcile bimfelf to their peculiar manners. Belides, his inquifitive turn of mind would not allow him to adopt that indiffer. ence to every fcientific inquiry which was one of the characteriftic diftinctions of the fect. He therefore attended upon other mafters, who profeffed to inflruct their dicciples in the nature and caufes of things. When Crates, difpleafed at his following other philofophers, attempted to drag him by force out of the fehool of Stilpo, Zeno
faid to him," "You may feize my body, but Stilpo has laid hold of my mind." After continuing to attend upon the leclures of Stilpo feveral years, he paffed over to other fchools, particularly to thole of Xenocrates and Diodorus Cronus. By the latter he was intructed in dialectics. He was to mucla delighted with this branch of ftuly, that he prefented to his mafter a large pecuniary gratuity, in return for his free communication of foane of his ingenious fubtleties. At laft, after attending aimoft every other mafter, he ofiered himfelf as a difiple of Polemo. This philofopher appears to have been aware, that: "Zeno's intention in thus removing from one fchool to another, was to collect materials from various quarters for a new fyttem of his own; for, when he came into Polemo"s Echool, he faid to him, "I am no ftranger, Zeno, to your Phcenician arts; I perceive that your defign is to creep llyly into my garden, and fteal away my fruit." Polemo was not miftaken in his opinion. Having made hinfelf manter of the tenets of others, Zeno determined to become the founder of a new fect. The place which he made choice of for his fchool was a public portico, adorned with the pictures of Polygnotus, and other eminent painters. It was the moft famous portico in Athens, and called, by way of eminence, Eroo, "the porch." It was from this circumflance that the followers of Zeno were called Stoics.

In his perfon Zeno was tall and flender; his alpect was fevere, and his brow contracted. His conftitution was feeble, but he preferved his health by great abtemioufnefs. The fupplies of his table confited of figs, bread, and honey; notwithftanding which, he was frequently honoured with the company of great men. In public company, to avoid every appearance of an affuming temper, he commonly took the Ioweft place. Indeed fo great was his modefty, that he feldom chofe to mingle srith a crowd, or wifhed for the company of more than two or three friends at once. He paid more attention to neatnefs and decorum in external appearance than the Cynic philofophers. In his drefs indeed he was plain, and in all his expences frugal; but this is not to be imputed to avarice, but a contempt of external magnificence. He fhowed as much refpect to the poor as to the rich; and converfed freely with perfons of the meanefl occupations. He had only one fervant, or, accerding to Seneca, none.

Zeno lived to the extreme age of 98 ; and at laft, in confeçuence of an accident, voluntarily put an end to his life. As he was walking out of his fchool he fell down, and in the fall broke one of his fingers; upon which he was fo affected with a confcioufnefs of infirmity, that, Atriking the earth, he faid, "Why am I thus importuned? I oboy thy fummons;" and immediately went home and flrangled himielf. He died in the frit ycar of the 129th Olympiad. The Athenians, at the requeft of Antigonus, erected a monument to his memory in the Ceramicum.

We ought not to confound the two Zenos already mentioned with

Zeno, a celebrated Epicurean philofopher, born at Sidon, who had Cicero and Pomponius Atticus for his difciples, and who wrote a book againft the mathematics, which, as well as that of Poflidonius's refutation of it, is loft ; nor with feveral other Zenos mentioned in hiftory.

ZENOBIA, queen of Palmyra. See Palmyra.

ZeOLite, a mineral fubfance. See Miniraiocy Index.

ZEPHANIAH, a canonical book of the Oid Teftament. See Scripture, \(n^{\circ} 79\).

ZEPHYR, the WESTIVInd, or that which blows from the cardinal point of the horizon oppofite to the ealt.

ZEPHYRUS, one of the Pagan deities, was repre. fented as the fon of Aurora, and the lover of the nymph Chloris, according to the Greeks, or of Flora according to the Romans; and as prcfiding over the growth of fruits and flowers. He is defcribed as giving a refrefhing coolnefs to the air by his foft and agreeable breath, and as moderating the heat of fummer by fanning the air with his fillen wings. He is depictured under the form of a youth, with a very tender air, with wings refembling thofe of the butterily, and with his head crowned with a variety of flowers. As the poets of Greece and Kome lived in a warm climate, they are lavih in in their praife of this beneficent deity, and under his name deficribe the pleafure and advantage they received from the weftern breezes.

ZEndA. See Caxis, Mammalia Index.
ZERTA, the Zerte, a fifly caught in the rivers of Italy and fome other places, of the figure of the chub, and called by authors capito anodromus, and the blike. It feldom grows to more than two pounds weight, and at times lives in rivers, at times in the fea; and is efteemed a very well tafted fifh, efpecially a little before the feafon of its fpawning. The zerte is that fpecies of cyprinus defcribed by Gefner and others under the name of capito anodromus.

ZEST, the woody thick Nkin quartering the kerneI of a walnut; prefcribed by fome phyficians, when dried and taken with white wine, as a remedy againf the gravel.

Zest is alfo ufed for a chip of orange or lemon peel; fuch as is ufually fqueezed into ale, wine, \&c. to give it a flavour; or the fine oil which fpurts out of that peel on Equeezing it.

ZEUGMA, a figure in Grammar, whereby an ad\(j \in\) Etive or verb which agrees with a nearer word, is alfo, by way of fupplement, referied to another more remote.

ZEUS, a genus of fifhes of the order of thoracici. See Ichthyology Index.

ZEUXIS, a celebrated painter of antiquity, flourihed about 400 years before Chrift. He was born at He raclea; but as there have been many cities of that name, it cannot be certainly determined which of them had the honour of his birth. Some learned men, however, conjecture, that it was the Heraclea near Crotona in Italy. He carried painting to a much higher degree of perfection than Apollodorus had left it; difcovered the art of properly difpofing of lights and chades, and particularly excelled in colouring. He amafied immenfe riches; and then refolved to fell no more of his pictures, but gave them away; faying very frankly, "That he could not fet a price on them equal to their value." Before this time he made people pay for feeing them; and nobody was admitted to fee his Helena without ready money, which occafioned the wags calling his picture Helen the Courtexan. It is not known whether this Helen of Zeuxis was the fame with that which was at Rome in Pliny's time, or that which he painted for the inhabitants

Zeuxis inhabitants of Crotona to be hung up in the temple of that city，copying from each her greateft excellencies． Pliny obferves，that this admirable painter，difputing for
the prize of painting with Parrhafius，painted fome grapes fo naturally，that the birds flew down to peck them．Parrhafius，on the other hand，painted a curtain fo very artfully，that Zeuxis，miflaking it for a real one that hid his rival＇s work，ordered the curtain to be drawn afide，to nlow what Parrhafius had done；but having found his miftake，he ingenioully confeffed him－ felf vanquifhed，fince he had only impofed upon birds， while Parrhafius had deceived even a mafler of the att． Another time he painted a boy loaded with grapes； when the birds alfo flew to this picture，at which he was vexed；and confeffed，that this work was not fufficiently finithed，fince had he painted the boy as perfectly as the grapes，the birds would have been afraid of him．Ar－ chelaus，king of Macedon，made ufe of Zcuxis＇s pencil for the embellifhment of his palace．One of this pain－ ter＇s fineft pieces was a Hercules frangling fome fer－ pents in his cradle，in the prefence of his affrighted mo－ ther：but he himfelf chiefly efteemed his Athleta，or Champion，under which he placed a Greek verfe that afterwards became very famous，and in which he fays， ＂That it was eafier to criticife than to imitate the pic－ ture．＂He made a prefent of his Alcmena to the A． grigentines．．Zeuxis did not value himfelf on fpeedily finifhing his pi\＆tures；but knowing that Agatharchus gloried in his being able to paint with eafe and in a lit－ tle time，he faid，＂That for his part he，on the con－ trary，gloried in his flownefs；and，if he was long in painting，it was becaufe he painted for eternity．＂Ver－ rius Flaccus fays，that Zeuxis having painted an old wo－ man，he laughed fo very heartily at the fight of this pic－ ture，that he died：but as no other of the ancients has mentioned this particular，there is the greateft reafon to believe it fabulous．Carlo Dati has compofed in Ita－ lian the Life of Zeuxis，with thofe of Parrhafius，Apel－ les，and Protogenes．This work was printed at Florence in 1667 ．

Zinc． Palefline or Canaan；but according to Wells，on the call of Edom，to the north of Ezion－gaber．

ZINC，a metallic fublance，formerly confidered as one of the brittle metals；or，according to the diftinction of the older chemifts，a fomi－metal or s＇1 imperfect me－ tal，becaufe it was found to be dellitute of tome of the properties of other metals which were confidered as per－ fea．For an account of the properties and combina－ tions of zinc，as they were then known，－fee Chemr． stry Index；and for the hillory of its ores，fee Mine－ ralogy Index．
But in the progrefs of chemical difoovery it las been found that zinc is not a lefs perfect metal than others； for in the year \(\mathbf{1 8 0 5}\) ，it was announced that a patent was granted to Mefirs Iobfon and Sylvelter of Shef－ field for a method of manufacturing zinc．From their difcovery it appears，that zinc raifed to a temperature of between \(210^{\circ}\) and \(300^{\circ}\) of Fahrenheit，is not only very malleable，but may be paffed through rollers，or drawn into wire．After the metal has been treated in this manner，it does not return to its former brittlenefs，but continues foft，flexible，and extenfible，and may be ap－ plied to many ufes for which this metal was before thought unfit＊．
We muft，however，notice，that a prior claim to the dif covery of rendering zinc ductile and malleable，has been made by Mr Lowry，in favour of a Mr Sheffield of Somerf－ town．Twenty years before the time of Meffrs Hobfon and Sylvefter＇s patent being announced，Mr Sieffield，in making an affay of fome blende，was impatient to exa－ mine the metal，ftruck an ingot for the purpofe of break－ ing it while it was yet hot，but was much furprifed to find that inftead of being brittle，and breaking with the ufual fracture of zinc，it was extremely tough，and when he fucceeded in breaking it，after many bendings backward and forward，it exhibited a fteel－grained fibrous texture．At firt he doubted of the metal be－ ing zinc，but he repeated the experiment on what he knew to be pure metal，and obtained the fame refult； and from this he concluded that zinc at a certain tem－ perature is equally malleable and ductile with other metals．This he found to be the cafe by drawing it into wire，and laminating it between rollers，by which he produced plates not exceeding the \(\frac{x}{200}\) of an inch， and poffefling the ftrength and tenacity of filver \(t\) ．
Since the time that our article Chemistr y was print－ ed，the decompofition of potall，foda，the alkaline earths， and fome other bodies which were formerly confidered as fimple，or were only conjectured from analogy to be compound，has been effected by Mrr Davy ；and as we were difpofed to entertain hopes that fomething new might be added to the unexpected and brilliant difcoveries of that celebrated chemift，we have deferred， till near the clofe of our work，giving any account of them．This is the reafon that the fact was merely an－ nounced under the words Potash and Soda，and a re－ ference made to Gafuanic Trovgu，under which it was intended to give a fhort defcription of the apparatus， employed in the experiments which led to the difcoveries alluded to．For the fame reafon we were induced to male a farther reference to this place，becaufe zinc is
one of the metallic fubfances ufually employed in the conftruction of galvanic apparatus. We fhall therefore here employ a ferv pages, if, In a defcription of the improvements which have been made in the conftruction of galvanic apparatus; and, 2 d , We fhall lay before our reaters a view of the dicoverics in galvanic electricity fince the treatifes on Chemistry and Galvanism in this wurk were printed.

Golvanic Apparatus.-A very confiderable improvement has been made on the conftruction of gaivanic batteries; by which they are rendered, not only more convenient and manageable, but far more powerful. Under the äticle Galvaxism, we have defcribed particularly the conftruction of the galvanic trough, and we have noticed that the foldering of the plates of zinc and copper employed for this purpofe was attended with conifderable difficulty. In the new method of confiruction the plates are not-foldered together, but are merely connected by means of a metallic arc. In this way each pair of plates can be removed from the trough at pleafure, for the purpofe of examining and cleaning them. The new apparatus is conftructed precifely on the fame principle as the couronne de Tafles, propored by Volta, and defcribed at p. 333 of Galvarism. The trough employed in this apparatus is prepared in the fame way as when the plates of zinc and copper foldered together were fixed in it by means of cement; but in place of the metallic plates, plates of glafs, or fome other non-conducting fubflance, are introduced and fecured by cement, fo that there thall be no communication between the different cells into which the liquid is introduced. The plates of zinc and copper co:nnected by means of the metallic arc, at the difance of docut half an inch, are placed in diferent cells, having a plate of glafs between each pair of plates. Each cell then contains a plate of each of the metals, which are unconnected, excepting through the medium of the liquid which is to be the conductor of the electricity. It is fearcely neceffary to mention. that the proper order of arrangement ftall be obferved, fo that through out the whole trough or battery there fhall be a feries of zinc, copper, and liquid.

Befide the conveniency and fimplicity of this mode of conftucting galvanic troughs, it poffefes this farther idvantage of being more powerful, becaufe inftead of one furface of the plates, as in the former conftruction of this apparatus, both furfaces are expofed to the action of clectricity, and therefore the power is greatly increafed. A farther improvement, it is faid, has been made in conllructing batteries of this kind, which confitts in emploving troughs of Wedgwood's ware, with partitions of the fame material, intead of wooden troughs with partitinns of glafs. This improvement was firt fuggefted by Dr Babington.

The following is the account of the conftruction of galvanic apparatus, with the view of afcertaining in what way the greateft effect might be produced, with the leaft watte of power and expence. Tlie experiments which we are now to mention were made by Ms Children *. For this purpofe a battery was conflucted on the new method, with plates of copper and zinc, connected by leaden fraps. foldered on the top of each pair of plates. T'wenty pairs of plates were employed, and cach plate was four feet high by two feet wide. The whole extent of furface expafed amounted to 92,162
fquare inches; the trough was made of wood, with wooden partitions, covered with ecment, to refit the action of the acid employed. The battery was charged with a mixture of three parts of fuming nitrous, and one of fulphutic acid, diluted with thinty of water; the quantity employed was 120 gallons. With this appa. ratus the following experimerts were made.

Exper. 1. Eighteen inches of platina wire, of onethirticth of an inch diameter were completely fufed in about twenty feconds. Exper. 2. Three feet of thie fame wire were heated to a bright red, vifible by firong day-light. Exper. 3. Four leet of the lame wire were rendered very hot, but not perceptibly red by day-light. Exper. 4. Charcoal burnt with intenfe brilliancy. Exper. 5. Ten inches of iron-wire of \(\frac{1}{70}\) th of an inch diameter, were barely fulod; three fect of the fame wire were not ignited. Faxper. 6. No effect was produced on imperfect conductiors. Exper. 7. The goldleaves of the electrometer were not affected. Exper. 8. When the cuticle was dry, no fhock was given by the battery, and it was fearcely perceptible when the akin was wet.

To contraft the effects of this apparatus with anoiher diffring in the fize and number of plates, the author employed 200 pairs of plates, each about two inclies ifuare, placed in half pint pots of common queen's ware. The fame liquid was employed, with the addition of a frefh portion of fulphuric acid, in the :roportion of about a quarier of a pint to a gallon. The experiments with this apparatus gave the following refults.

Exper. 1. Potafi and barytes were readily decompofed. Exper. 2. The metallization of ammonia was produced with great facility. Exper. 3. Charcoal was vividly ignited. Exper. 4. The gold leaves of the electrometer diverged confiderably. Exper. 5. After the battery was in action three hours, it gave a vivid fpark; at the end of 24 hovrs it metallized ammonia; at the end of 41 hours it was nearly exhaufted. From the refults of thefe experiments, Mr Children concludes, that the theory of the mode of action of the voltaic battery propofed by. Mr Dary is confirmed, namely, that the intenfity increafes with the number, and the quantity with the extent of the feries. This is proved by the efficets produced on the platina and iron wires, in the ift and 5 th experiments with the large battery, as well as by the experiments on imperfect conductors in the fmall apparatus; for as the platina wire is a perftet conductor, and not liable to oxidation, it allows the electricities to be freely tranfmitted, and from the immenfe quantity given out from a furface of fuch extent, they evolve, on their mutual annihilation, heat fufficient to raife the temperature of the platina to the point of fufion. But a very fmall portion of the eledricity paffes through the iron wire, in confequence of its cafy oxidation, and the tbin coat of oxide formed on its furface. This arifes from the low ftate of the intenfity of the electricity, as appears al fo from its want of power on the gold leares of the \(c\) lectrometer. Fiom the fame deficient intenfity, the decompofition of barytes could not be effected by the large hattery, and the fame battery exhibited a very weak action on imperfect conductors; but the fmall battery exerted creat power on that clafs of bodics, and decompofed them readily, althourgh its furface was 30 times lefs than the funface of the great battery; but the mum-

Zinc. ber of plates' was nearly ten times greater. Another circumfance, of confiderable importance in conducting experiments by means of the galvanic battery, is here noticed by the author; that the long continued action of the frall battery was owing to the large capacity of the cells containing a proportional quatuty of liquor. And befide this advantage he adds, that with very large combinations, a certain diftance between each pair of plates is albfolutely neceffary to prevent fontaneous difcharges, which are accompanied with vivid thathes of electric light. This happened to the author with a battery of 1250 four-incl plates, conllructed according to the new method.

From the experiments and obfervations, fome of whiclo we have detaited, and for others we refer to the paper itfelf, the author conchudes with the following remarks: " The abfolute effect of a voltaic apparatus ficms to be in the compound satio of the number and fize of the plates. The intenfity of the electricity being as the former, the quantity given out as the latter, cunfequently regard mult be had, in its confruction, to the purpofes for which it is defigned. For experiments on imperfect conductors, very large plates are to he preferred, a fmall number of which will probably be fufficient; but where the refiftance of imperfect conductors is to be overcome, the combination muft be great, but the fize of the plates may be fmall : but if quantity and intenfity be buth required, then a large number of large plates will be neceflary. For general purpofes, four inches \{quare will be found to be the moft convenient fize *"

Difcoveries in Gakranifm.-At the clofe of the article Galvanism, we noticed fome experiments which were made about the beginning of the year 1805 , which feemed to lead to the conclufion, that muriatic acid and foda were formed by means of galvanic electricity. In experiments on the decompofition of water, which was fuppofed to be in a ftate of the utmolt purity, the appearance of muriatic acid and foda was adduced in fupport of this opinion. The accuracy of this conclution, which feemed to be at variance with known facts, excited doubt, and probably led to the inveftigation which was undertaken by Mr Davy, and carried on with great ingenuity and addrefs by the fame philofopher, fill it terminated in the brilliant difcoveries, an account of which we are now to detail. Mr Davy's refearches in galvanifm, an account of which he laid before the Roval Socieiy in a memoir entitled, On fome Chemical Agencies of Electricity, may be confidered as the firf ftep in this train of inveitigation.

With the view of difproving the accuracy of the experiments in which the generation of acids and alkalies was fuppofed to have been effected by means of galvanifr, Mr Davy employed agate cups, (fig. 1.), of a cylindrical form, and containing about one-fourth of a cubic inch each. The cups were boiled for fome hours in diftilled water, and a piece of white tranfparent amianthus, which bad been treated in the fame way, was sade to connect them. They were then filled with diflilled water, and expofed bv means of two platina wires, to a current of clectricity, from \(15^{2}\) pairs of plates of copper and zinc, four inches fquare. The liquid employed was a folution of alum. The action continued 48 hours, and the procels was then examined. Paper tinged with litmus intraduced into the tube containing the pojitive wire, was reddened; paper coloured
by turmeric placed in the other tulse, had its colour deepened; the acid matter produced a Collit terbidity in a fulution of nitrate ul filver; the thad from the negative tube retained the property of atlecting the turmeric after being boiled, and indeed became more vivid as the quatitity was diminifbed by evaporation. Carhonate of ammonia was added, and the whole being dried, and expofed to a flrong heat, a minute quantily of white matter remained, which had all the propertics of carbunate of foda.

The lame experiment was repeated with glafs tubes, and the refult was, that the quantity of alkali ablained was 20 limes greater, but no traces of muristic aribl could be perceived. Mr Davy fufpecling that the ardate might contain a minute potion of faline matter, repeated the cxperiment four times. Jlic quannty of alkaline matter diminifhed in every operation, and i:n the latf procefs, although the battery had been leept ist great activity for three days, the fluid pofferd in a ilight degree only the power of acting on paper simsed with turmeric; but its alkaline property was very lenfible to litmus paper fightly reddened. 'I he acid matter in the other tube was abundant; it had a four tate, and produced no effect on Colution of muriate ot barytes, but left a black Atain from a drop on a polifhed plate of filver. Thus it appeared to be extremely diluted nitrous acid.

For the purpofe of making the experiment with greater accuracy, two holluw cones of pure guld (fig. 2.) Fig. 2. were employed, each containing about 25 grains of water. They were filled with dillilled water, connected by moiftened amianthus, as before, and expofed to the action of a battery of 100 pairs of plates of fix inches fquare. The liquid uled was a folution of alum, ard diluted fulphuric acid. In ten minutes the water in the negative tube changed litmus paper 10 a night b!ue, and the water in the politive tube produced a red tint. The procels having continted for \(1 \neq\) hours, the acid was found to increafo in quantity during the whols time, but the alkaline fluid in the other tuhe did res affect the tefts more than in the frft trial. The acid fecmed to be the pure nitrous, with an excefs of nitrous gas. The cxperiment was repeated, and the procels carried on for three days, and limilar refults were obtained. From thefe experiments it was concluded, that the difilled water containcd a minnte portion of faline matter, but fo minute indeed, that it was infenfible to the mott delicate chemical teits. This appeared to be the cafe by evaporating a quantity of the ditilled uater that was ufed, very flowly, 3t a heat below \(140^{\circ} \mathrm{F}\) alm renheit, in a filver tlill. A quantity of folid matter equal to feven-tenths of a grain, of a faline put metallic tante, was obtained. It feemed to be a mixture of uitrate of foda and nitrate of lead. Mr Dary then employed fome of the water collected in the fecond procefs of flow difillation, in another experiment with the gold tubes and comeeting amianthus. At the end of two hours the water in the negative tube had no effect on turmeriç paper; litmus, it could jut be perceised, was changed; but by heating the water ftrongly for two or three minutes, it was deprived even of this pover, and from this he fuppofes that it was owing to a frmall quantity of ammonia. A fimilar experiment was made with a portion of the fame water in the agate lubes, a:d precifely the fame refults were obtained. From thefe

\section*{Z I N}

Zinc.
experiments -Mr Davy fairly concludes, that the fixed
alkali is not generated during the procefs, but merely evolved, either from the folid materials employed, or from faline matter in the water.
Many experiments were made in veffels compofed of different fubitances, with the water procured by flow diftillation ; and in almoit every inftance fome fixed alkali appeared. When tubes of wax were ensployed, the alkaline ntatter was a mixture of foda and potath, and the acid matter, a mixture of fulphuric, muriatic, and nitric acids. A tube of refin afforded alkaline matter, which was principally potalh. A cube of Carya:a marble of about an inch, having an aperture in its centre, was placed in a platina crucible, which was filled as high as the upper furface of the cube, with the puified water. The aperture was filled with the fame liquid, and the crucible was pofitively electrified by a powc: ful battery, and the negatively tlectrified wire introduced into the aperture. Fixed alkali and line were obtaired in this experiment; the quantity of alkali diminihing as the experiment was repeated, and after II proceftes, each continued for two or three hours, difappeared altogether. The quantity of lime-water obtained was uniform.
When 500 grains of this marble were analyzed, they afforded about threc-fourths of a grain of fixed faline matter, having foda for its bafe. Sufpecting that the Carrara marble might have been recently expofed to fea water, Mr Davy fubjected to a fimilar experiment, a piece of granular marble from the mountains of Donnegal, and by means of negative electricity he obtained fised alkali. Argillaceous fchifus from Cornwall gave the fame refuit, and ferpentine and gray wacken both afforded foda.

In other experiments Mr Davy fubjected other bodies to the action of the fame power, with the view of effesting a decompofition. Thus, tho cups of compact fulphate of lime, each containing about \(I_{4}\) grain meafures of water, were connected by fibrous fulphate of lime moifened with pure water. The cups were filled with the fame fluid, and they were introduced into the circuit of a galvanic battery with 100 pairs of plates of fix inches. In five minutes the water in the pofitive cup became acid, while that in the oppofite cup tinged turmetic. An hour after, a faturated folution of lime was formed in the negative cup, and the other contained a folution of fulphuric acid of moderate ftrength.

Two cubical pieces of cryfallized fulphate of frontites, of about an inch, with a hole drilled im each, capable of receiving eight grains of water, were plunged in pure water, in a platina crucible, and the level of the fluid was kept a few jines below the furface of the cubes. The holes in the earthy mineral were filled with pure water, and two platina wises were introduced into them. At the end of thirty hours the fluid in the cavity of the negative fide precipitated folution of fulphate of potah, and fulphuic acid appeared in the other.

Two pieces of fluate of lime, having each a cavity, and connected by moin anbellus, were fubjected to a limilar experiment. The decompofition was flow; but in two days a folution of lime appeared in the one tube, and an acid in the other, which precipitated acetate of lead, and left a fpot upon the glafs, from which it was cyaporated, fo that it muft have been fluoric acid.

Compaet zeolite being prepared in the fame way, and electrified in the fame manner as the cube of Carrara marble; afforded foda and lime. Lepidolite, by fimilar treatment, gave potaih; and an alkaline matter, which feemed to be a mixture of foda, potath and lime, was extracted from a piece of vitieous lava from Mount Etna.

The decompofition of faline bodies, which are foluble in water, was more rapid. A diluted folution of fulphate of potafh introduced into the agate cups connected by amianthus moiftened with pure water, being electrified by a battery with 50 pairs of plates, produced in four hous a weak folution of potalh in the negative cup, and a folution of fulphuric acid in the pofitive cup. Similar phenomena were obferved when fulphate of foda, nitrate of potath, nitrate of barytes, fulphate of ammonia, phofphate of foda, fuccinate, oxalate, and benzoate of ammonia and alum, were employed. The acids in a certain time collected in the tube containing the pofitive wire, and the alkalies and earths in the negative tube. Solutions of the muriatic falts, fubjected to decompofition by the fame procefies, uniformly afforded oxymuriatic acid on the pofitive fide.

Saturated faline folutions were moft rapidly decom. poled, but the fmalleft proportion was allo acted on. Thus, if a piece of paper tinged with turmeric be plunged into pure water, in a proper circuit, in contant with the negative point, the minute quantity of faline compound contained in the paper, produces inftantly a brown tint near its point of contact. Acid appears allo from litmus paper at the pofitive furface.

Experiments were made with the view of afcertaining whether in thefe proceffes the feparation of the confituent parts was complete, from the laft portions of the compound. The following experiment hows that this is the cale. "A very weak folution of fulphate of potaft, containing 20 parts of water, and one part of faturated folution at \(64^{\circ}\), was electrified in the two agate cupe, by the power of 50 pairs of plates for three days; the connecting amianthus which had been moifened with pure water, was removed, wathed with pure water, and again applied twice every day. By this precaution the prefence of any neutral falt that might adhere to it, and difturb the refults, was prevented. The alkali obtaincd in this procefs in the folution had the properties of pure potahn, and when it had been faturated with nitric acid, it gave no turbidnefs by mixture with folution of muriate of barytes; the acid matter expofed to a ftrong heat, evaporated, without leaving any refiduum."

Mr Davy then made experiments on the transfer of certain of the conftituent parts of bodies, and allo on the pafrage of acids, alkalies, and other fubftances, through various attracting chemical nuenftrua, by means of electricity, and in the le experiments he obtained many curious and interefting refults; but for an account of them, as well as of his obfervations on the different phenomena, and on the mode of decompofition and tranfition, we muft refer to the memoir itfelf.

After the invefligations in which Mr Davy had been occupied, and the fingular and unexpected refults which he obtained, he ventured to conclude, from the general principles on which the phenomena might be explained, that the new methods of procecding would lead to a more intimate knowledge concerning the true elements

\title{
Z I N
}
of bodies. Accordingly, in November 1807, he laid before the. Royal Society a mof interclting detail of an elaborate feries of expeliments on the decompofition of the a!kalies.

\section*{Decompofition of the Alkalics.}

In the firt attempts that were made on the decompo. fition of potafh, Mr Davy employed an aqueous folution, faturated at a common temperature. It was expofed to the action of a powerful galvanic battery, compofed of 24 plates of copper and zinc of 12 inches fquare, 100 plates of fix inches, and 150 plates of four inches feure, charged with folutions of alum and nitrous acid. The action was very intenfe; a great deal of heat and violent effervefcence were produced, but the water only of the folution was affected, and its hydrogen and oxygen were difengaged. Potalh in the flate of igneous fution, in a fpoon of platina, was next fubjected to the action of a battery of 100 plates of fix inches, highly charged. The fpoon was connected with the pofitive fide. In this experiment fome brilliant phenomena were produced. The potan appeared to be a good conductor; and, while the communication was preferved, a molt intenfe light was emitted from the negative wire, and a column of flame, feemingly owing to the developement of combuttible matter, arofe from the point of contact. When the order was reverfed, and the platina fpoon was connected with the negative fide, a vivid and conftant light appeared at the oppofite point. There was no inflammation round it; but aeriform globules, which inflamed in the atmofphere, rofe through the potah. The platina was confiderably acted on.

Although potafh, when perfeetly dry, be a non-conductor, it acquires a conducting power by being nlightly moiftened. A fmall piece of pure potath expofed for a few feconds to the atmofphere, was placed on a dife of platina connected with the negative fide of a battery of 250 plates of fix and four inches, in a fate of intenfe activity. A platina wire from the oppofite fide was brought in contact with the upper furface of the alkali. A vivid action foon took place. The potath fufed at both points of electrifation; a violent effervefcence appeared at the upper furface; but at the lower or negative furface no elattic fluid was emitted, but fmall globules like quickfilver were produced, fome of which burnt with explofion and bright flame as they were formed, and others remained and were only tarnifhed, and finally covered by a white film formed on their furfaces. Thefe globules were the bafis of potalh. The fame refults were obtained, when gold and other metals, plumbago, or charcoal, were employed; and the effects were the fame when the procefs was conducted in an exhaufted receiver.

Mr Davy alfo obtained the fame fubftance from potath, fufed by means of a lamp, and placed in glafs tubes confined by mercury, and furnifhed with hermetically inferted platina wires, to tranfmit the electricity; but the glafs was rapidly diffolved by the action of the alkali, fo that the procefs could not be long carried on.

In thefe cxperiments on potath, the combuftible bafe was produced from the negative furface, and oxygen was evolved from the pofitive furface. The fame effects invariably followed, when the experiment was conducted above mercury. The fame thing was proved fynthetically, The combufible fubtance obtained from the
potafl had its metallic luftre deftroyed in the atmo. fphere, and a white cruft formed upon it. This cruf was found, upon examination, to be pure potafh; but this was lill farther confirmed by placing globules of the combuftible matter in tubes containing common air, or oxygen gas, confined by mercury. An abforption of the oxygen took place, and n crult of alkali was formed upon the globule. When the combuttible matter confined in given portions of oxygen, was ftrongly heated, a rapid combuftion, with a billiant white tlame, was produced, and the metallic globules were converted into a khite and Colid mals, which was found to be pure potalh.

To the combuftible matter thus ohtained from potaft, Mr Davy gave tho name of potafirm. From its Ilrong alfinity for oxygen, it was extremely difficult to preferve it unchanged, for the purpofe of examining its properties. The fubitance which he found to be lean affected, is newly dillilled naphtha. In this huid potaffum may be kept for many days neariy unaltered, and its plyyfical properties may be examined in the atmofphere, when covered by a thin film of it.

Potaffium, at \(60^{\circ}\) Falrenheit, is in the form of fmall globules, which have the metallic luftre and gencral appearance of mercury; at \(70^{\circ}\) it becomes more tluid, and at \(100^{\circ}\), different globules eafily run into onc. At \(50^{\circ}\) of Fahrenheit it is foft and malleable, and exhibits the luftre of polifhed filver. At \(32^{\circ}\) it becomes hard and brittle, and, when broken, prefents a cryftallized texture. To reduce it to vapour, it requires a red heat; and in proper circumfances, it may be fubjected to diftillation, without change. It is a good conductor of heat, and a perfect conductor of electricity.

In the properties now mentioned, potaffium approach. es nearly to the metals; but it is very different in its fpecific gravity. In naphtha of the fpecific gravity of .861 it rofe to the furface; and it did not fink in double diltilled naphtha, the fpecific gravity of which was about.770. From thefe and other experiments, Mr Davy eftimates the fpecific gravity of potaflium at 6 , fo that it is the lighteft fuid body known. In its folid form it is fomewhat heavier; but, even in this ftate, when cooled to \(40^{\circ}\) Fahrenheit, it fwims in double diftilled naphtha.

With the view of afcertaining the propertions of the conftituent parts of potalh, Mr Davy made two experiments, by fubjecting the metallic bafe to combuftion in oxygen gas. In the firt experiment, .12 of a grain of potaffum were employed; the combultion was made upon platina, and was rapid and complete, and the bafis appeared to be perfectly faturated. The refult of this experiment indicates 86.7 of bafis, and 13.3 of oxygen, in the 100 parts of potall. In another experiment, the refult he obtained was 85.5 of bafis, and 14.5 of oxygen. The mean of thefe two experiments is 86.1 of bafis, and 13.9 of oxygen, in 100 parts of potath.

The refults of the dacompofition of water by the bafis of the alkalies, which were more readily and perfectly obtained than thofe of their combuftion, exhibited the proportion of bafe to be \(S_{4}\), and that of oxygen 16 ; but the mean of 86.1 of bafe, and 13.9 of oxygen, and 84 bafe and 16 oxygen, is 85 of potaffum and 15 of oxygen, which may be taken as the proportions of the elements of potah.

Mr Davy's difcoveries have been confrmed by the
ingenious ingenious experiments of Thenard and Gay-Luffac. 'Thefe diflinguinted chemilts have decompofed potah by a different procefs. They introduced iron filings into a bent gun barrel, which was placed acrofs a furnace. A in'e with a nopcock, conlaining a quantity of folid potafh, is connecied witb one extremity of the gun barrel; to the other extremity there is attached a tube of fafety, containing mercury, for the purpofe of excluding the atmoipheric air, and allowing any gafeous matte: formed during the procefs to efcape. The potafh in the tube is to be kept cold by means of a frcezing mixture, till that part of the barsel containing the iton filings has been raifed to a white hat. The potaft is then fufed by applying heat, by means of a portable furnace; and it is allowed to pals through a frall opening, to come in contact with the iron filings, where it is decompofed, the oxygen of the potafh entering into combination with the iron, and the bafe paffing on to the other extrcmity of the tube in a flate of fublimation. At that extremity the metallic bafe is condenfed by the application of exceffive cold, and in this way the potaffium may be obtained at lefs expence, and in greater quantity, than by means of galvanifm. During this procefs, hydrogen gas is evolved, which, it is fuppofed, is owing to the decompofition of the water contained in the alkali. The potafium thus obtained is in the form of brilliant laminee, which adhere to the fides of the gun barrel. An alloy of the fame metal with iron is allo found in that part of the barrel containing the filings. Mr Davy has repeated this experiment, and he firds that the bafe obtained in this manner is heavier, and its melting point higher, than what is procured by means of galvanifm. This, it is fuppofed, may arife from its being combined with a fmall proportion of iron. The metallic bafe of foda was ohtained by a fimilar procefs.

But, according to the view which the French chemils have taken of thefe difcoveries, and the refults of their own expcriments, they conclude, that the metallic fubfances derived from the alkalies are not fimple, but are compounds of the feveral bafes with hydrogen.

Another method of decompofing potahh, and obtaining its bafe, which is flill fimpler, has been followed by Curaudau. In this procefs the decompolition is effeted by charcoal. A misture of carionate of polath is made with four or charcoal and lin:feed oil. This mixture is introduced into an iron or earthen tube or retort, and calcined, by gradually raifing the heat, till a bluifh light be feen in the infide of the vefiel. Soon after an abundant evolution of vapour takes place, which is the bafe of the alkali, to he collected by intuoducing a clean iron rod, on which it condenfes. Core mun be taken to withdraw the rod before it is too hot, and to plunge it in oil of turpentine, under the furface of which the metallic cruft on the rad may be feparated. In this way a quan?:'y of potaffium may be procured. The bafe of foda is obtained by a fimilar procefs.
Fig. 3. Fig. 3. is a reprefentation of the apparatus emploved by the French chemift in decompofing potall. ABCE: is the gun barrel laids acrofs the furnace, with its apparatus; \(D\) is the furnace, and F is the pipe of the bellows.

Fig. 4. is a fection of the tube containing the potafh.

But the chemical relations of potaffium are not lefs extraordinary than its rhyfical properties. It conblines
flowly with oxygen, and without flame, at all tempcratures below that of its vaporization. At this pione com. buftion takes place, with a brilliant white light, and intonfe heat. When it is heated flowly in a quantity of oxygen gas, which is not fufficient for its complete faturation, and at a temperature below that of inflammation, as for inflance \(400^{\circ}\) of Fahrenheit, it changes to a red brown colour, and the fulid form, confifing pattly of potaih, and partly of its bafe, is of a grayin colour. When expofed to watcr, or again heated in frella quantities of air, the whole is converted into potafti. When dry potafh and potaffium are fufed together under proper circumflances, the bafe is deprived of its metallic fplendour, and the two fubflances unite into a compound of a red brown colour when fluid, and of a dark gray when folid. This compound, when expofed to the air, foon abforbs its full proportion of oxygen, and is wholly converted into potafh. The fubfance thus formed feems to be in a lower thate of oxidation, fo that it is to be confidered as an oxide of potaflium with a fmaller proportion of oxygen.

When potaflium is introduced into oxymuriatic acid gas, it burns fpontaneoully with a bright red light, and a white falt is formed, which is muliate of potan? When a globule of potaffium is heated in hydrogen gas, at a degree below its point of vaporization, it feems to difolve in it, for the globule is diminithed in volume, and the gas explodes with alkaline fumes, and bright light, when brought into the air; but, by cooling, the potaffium is wholly or principally depofited, for the gas is deprived of its pioperty of fontaneous detonation.

When potaffium is thrown into water, it decompoles it with great violence; an infantaneous explofon, with brilliant flame, is produced, and a folution of pure potath is obtained. In thefe experiments, a white ring of fmoke, gradually extending as it rifes in the air, is produced, fimilar to the phenomenon of the combufion of pliof pliorated hydrogen. When a gloioule of the bafis of potall is placed upon ice, it inflantly burns with a bright flame; part of the ice is melted, and in the cavity there is found a folution of potafl.

By placing a globule of potaflium upon moiitened paper, tinged with turmeric, the monent that it comes in contact with the water, it burns, and, moving rapidly upon the paper, leaves behind it a deep redidith brown trace, thms demonftrating, in a very fimple manner, the production of the alkali by the decompofitions of water.

Potaffum readily decompofes the fmall quantities of water contained in alcohol and ether, even in thcir purelt ftate. As potafl is infoluble in ether, when the bafe is thrown into it, oxygen is furnifhed to it, and hydrogen gas evolved, and, as the alkali is formed, the ether becomes white and turbid. It is obferved, that the energy of action of potaffium in ether and alcohol, is proportional to the quantity of water which they contain, and hydrogen and potafl are always produced.

When potaflum is thrown into folutions of the mineral acids, it inflames and burns on the furface, and when plunged, by proper neans, beneath the furface envcluped in potafh, furrcunded by naplitha, it acts upon the oxygen with great intenfity. In fulphuric acid, a white \(\mathrm{f}_{\mathrm{d}}\) line fubfance, covered with a yellow coating, which is fuppofed to be fulplate of potefh ferrounded with fulphur, and a gas, laving the finell of fulphurous acid,

Zine.
and whech is probably a mixture of that fubfance with hedrogen gas, are formcd. When potafium is thrown into nitrous acid, nitate of potah is formed, ard nitrous gas is lirengaged.

Potafinm readily combines with phofphorus and fulphur. When preffed upon a piece of plofphorus, they both become fluid, enter inio combuflion, and produce phofplate of potaft. When the experiment is made upon naphtha, no gareous fubltance is given out ; the compound has the appearance of a metallic phofphuret, is of the colour of lead, and has the luftre of polinied lead. Expofed to the air at common temperatures, it combines flowly with oxygen, and is converted intu plof phate of potafh. When heated upon a plate of platina, it gives out fumes, but docs not burn till it eaches the temperature of the rapid combution of poraffum.

When potafium is brought into contact with fulphur in fufion, in tubes filled with the vapour of naphtha, they combine rapidly, with the evolution of heat and light. A gray fubfance is thus formed, which has the apperance of artificial luphuret of iron; if it be kept in fufion, it rapidly diffolves the glafs. When this experiment is made in a glafs tubc, hermesically fenled, no gas is difeng?ged, if the tube loe opened under mercury; but when it is made in a tube consected with a mercurial apparatus, a frall quantity of fulphurated hydrogen is evolved. When the combination is effected in the atmofphere, a great inflammation takes place, and fulphuret of notaln is formed, and by farther expofure to the air, it is at laf converted into fulphate of potafh.

When one part of potaffium is added 10 eight or ten of mercury, in bulk, at \(60^{\circ}\) of Fahrenleeit, they inflantly unite, and form a fubfance like mercury in colour, but lefs colevent. When a globule is nade to touch a glubule of mercury about twice as large, they combine with confiderable heat. The compound is fluid at the temperature of its formation, but, when cool, it becomes folid, with the appearance of filver. With the \(\frac{9}{3}-t h\) of potaffum to the weight of mercury, the amalgam is hard and brittle; but with one part of potafium, and 70 of nerrury, it is foft and malleable. Expofed to the air, thefe compounds abforb oxygen, and deliquefcent potafh is formed; and in a few minutes the mercury is revived. A globule of the amalgam, thrown into water, decompofes it rapidly with a hiffing noife; potafh is formed; pure hydrogen is difengaged, and the mercury remains free. This amalgam diffolves all the metals, and even acts on iron and platina.

When potaffum is heated with gold, filver, or copper, in a clofe veffel of pure glafs, a rapid action is produced, and the compounds thrown into water effect its decompofition; polafh is formed, and the metals are revived. Potafium forms an alloy with fufible metal, which has a higher point of fufion than the fufible metal itfelf.

Potaffum has little effect on colouriefs and recently diftilled naphtha; but, in naphtha, expofed to the air, it is foon oxidated, and an alkali which unites with the naphtha into a brown forp that collects round the globule, is formed. Potaffium acts flowly on the concrete oils, as tallow, fpermaceti, and wox, cven when heated; coaly matter is depofited, a little gas is evolved, and a foap is formed. On the fluid fixed oils the ef. fects are limilar, but take glace more flowly. With tic
affinance of lioat, volatile cils are rapidiy diccompofed by potaflum ; g:2s is cvolucd, and charcoal depofited.

Ihe metallic oxides, when heated in contaet with potaflum, are rendi'y reduced. When a fmall quantity of oxide of iron was heated with it, to a temperature approaching its poirt of diftillation, a vivid action toul: place. Nilali, in gray metallic particles, which effervefced in muriatic acid, appeared. The oxides of lead and tin were revived more rapidly, and with potaffum in excefs, an alloy was formed with the revived metal.

Potaflium readily decompofes fliat ghafs and green glafs, by a gentle heat. The metallic oxides are iedu. ced, and the alkali formed difulves the glafs. At a red heat, even the puref glass is acted on by potaffum; the oxygen in the alkali of the glafs feems to be divided between the potafisum employed, and the potafturn which is the bafe of the altali in the glafs, and thus cfieds an oxidation in the firn degrec.

Sodf.- When pure foda was fubjected in fimilar circumfances to the action of galvanifm, fimilar refults were obtained as from potafh; but the decompofition required a more intenfe action in the battery, or it was neceflary to have the alkali in thinner and fmaller pieces. Potaflum remained Huid at the temperature of the atmofphere, at the time of its produation; but the bafe obtained from fcda, which was fluid in the degree of heat of the alkali during its formation, became folid on cooling, snd exbibited the luttre of filver. With a bat tery ol 100 pairs of plates of fix inches, in full activity, the decompofition of pieces of foda of ahout 15 or 20 grains in weight only could be effected ; and it was neceffary alfo that the diffance between the wires fhould not exceed one-cighth or onc-tenth of an inch. Put when 250 pairs of plates were employed, highly charged for the dccompofition of foda, the globules often burnt at the moment of their formation, and fomctimes exploded and feparated into fraller globules, which darted rapidly through the air, in a fate of vivid constuftion, prodticing a beautiful effect of continued jets of fire.

When the melallic bafe which is ohtained from foda, and which Mr Davy has denominated fodium, was expofed to oxygen, it was converted into foda; and when this procefs was conducted by frongly heating the bafe in a giren portion of oxygen, a rapid combultion wilh a billiant white flame was produced, and the metallic globule was converted into a white folid mafs, which was found to be foda. The oxygen gas was abforbed during the operation, and nothing was given out which affected the purity of the refidual air.

The theory of the decompofition of the alkalies is flated by Mr Dary in the following words. "As in all decompofitions of cempound fubftances which I had previouly examined, at the fame time that combunible bafes were deweloped at the negative furface in the elcetrical circuit, oxygen was produced, and evolved or carried into combination at the poitive furface, it was rea. fonable to conclude, that this fubitance was generated in 2 fimilar manncr by the elcetrical action of the alkali ; and a number of experiments made above mercury, with the apparatus for excluding external air, proved that this sas the cafe. When folid potafh or fode, in its conducting nate, was included in gints tubes, furnifhed mith electrifed platinx wises, the neti fubfances

\section*{Z I N [ 792 ] Z I N}

Zinc. were generated at the negative furfaces; the gas given out at the other furface proved, by the moft delicate examination, to be pure oxygen; and, unlefs when ex. cefs of water was prefent, no gas was evolved from the negative furface.

For the purpofe of determining the proportions of the elements of foda, Mr Davy made fimitar experiments to thofe by which he afcertained the proportions of the bale and oxygen of potafh. By fubjecting fodium to combuftion in oxygen gas, it appeared that 100 parts of foda are compofed of 80 of metallic bafe, and 20 of oxygen; but the refults of its oxidation by the decompofition of water, indicated the proportions to be 23 of oxygen, and 77 of bale. By taking the mean proportions, obtained from the refults of the two fets of experiments, the elements of foda may be eftimated at \(7^{8.5}\) of metallic bafe, and 21.5 of oxygen.

Sodium, which remains folid at common temperatures, is white and opaque; and examined under a film of naphtha, has the luftre and appearance of filver. It is very malleable, and fofter than common metallic fubftances. With a flight preffure it fpreads into thin leaves, and a globule of one-tenth or one-twelfth of an inch in diameter, is eafily fpread over a furface of one-fourth of an inch; and different globules are eafily made to adhere, and form one mals by ftrong preffure. This property of welding which belongs to iron and platina at a white heat only, is not diminifhed when fodium is cooled to \(32^{\circ}\) Fahrenheit.

Sodium, like potaffum, is a conductor of electricity and heat, and fmall globules fubjected to galvanifm fnflame and burn with bright explofions. Sodium finks in naphtha of fpecific gravity .861; but by mixing perfectly about 12 parts of naphtha, and five of oil of falfafras, the fodium remains at reft in any part of the fluid. This makes its fpecific gravity \(=\) about .9348 , water being taken as 1 . The particles of fodium lofe their cohefion at \(120^{\circ}\) Fahrenheit. It becomes quite fluid at \(180^{\circ}\), fo that it readily fufes under boiling naphtha. The temperature at which it is volatilized is not afcertained, but it remains fixed in a fate of ignition at the point of fufion of plate glafs.

The chemical relations of fodium are analogous to thofe of potaffium, but with fome characterific differences. Expoled to the atmofphere, it is immediately tarnifhed, and is gradually covered with a white craft, which is pure foda. It combines flowly with oxygen, and without any luminous appearance at common temperatures. When heated, the combination is more rapid, but no light is emitted till it acquire a temperature near that of ignition. The flame in oxygen gas is white, and it fends forth bright fparks, producing a very beautiful effect; in common air, the colour of the light is like that of the combuttion of charcoal, but brighter. When fodium was heated in hydrogen gas, it feemed to have no action on it.

Sodium burns vividly in oxymuriatic acid gas, giving out numerous farks of a bright red colour; a faline matter is produced, which is muriate of foda. When fodium is thrown into water, it produces a violent effervefcence with a loud hifling noife; it combines with the oxygen of the water to form foda, which is diffolved, and its hydrogen is difengaged. During the procefs there is no luminous appearance; but when fodium is thrown into hot water, a more violent decompoftion
takes place. A few fintillations are obferved at tire furface of the water, which is owing to fmall particles of the bafis which are thrown out of the water, heated to tuch a degree as to burn in pafling through the atmofphere. But when a globule of fodium is brought into contact with a fmall particle of water, or with moiftened paper, the heat produced is ufually fufficient for its combultion, as in this cafe there is no medium to carry off the heat rapidly.

Sodium produces fimilar effects with potaffium when brought into contact with alcohol and cther. It ads with great energy on the ftrong acids; with nitrous acid it produces a vivid inflammation, and with muria. tic and fulphuric acids, great heat, but no light, is generated. The effects of fodium and potaftium on the fixed and volatile oils, and naphtha, are quite analogous; but the appearances of the faponaceous compounds are fomewhat different, the combinations with fodium being of a darker colour, and apparently lefs foluble.

Sodium alfo exhibits two degrees of combination with oxygen; the firf is of a deep brown colour, which is fluid when produced, and becomes a dark gray folid on cooling. By attracting oxygen from the air, or by the decompofition of the water, it is converted into foda.

Sodium forms compounds with fulphur and phofphorus. In clofe veffels filled with the vapour of naphtha, it enters into combination with fulphur, giving out during the procefs a vivid light and heat, and often attended with explofion, from the vaporization of a portion of fulphur, and the difengagement of fulphurated hydrogen gas. The fulphuret of fodium is of a deep gray colour. In its combination with phofphorus, the compound obtained has the appearance of lead, and by ekpofure to the air, or by being fubjected to combution, the phofphuret of fodium is converted into phofphate of foda.

Sodium forms compounds with the metals. In the proportion of one-fortieth with mercury, a compound is obtained, which is of the colour of filver, and remains folid; the combination is accompanied with confiderable heat. Sodium forms an alloy with tin, without producing any change of colour, and it has fome actions upon lead and gold when heated; but in its fate of al. loy it is foon converted into foda, by expofure to the air, or by the action of water, which it decompofes with difengagement of hydrogen. The amalgam of mercury and fodium feems to be capable of forming triple compounds with fome other metals; and it would appear that iron and platina remain in combination with the mercury, after thcy are deprived of the fodium by expofure to the air. The fame amalgam of fodium and mercury likewife forms combinations with fulphur; the triple compound thus obtained is of a dark gray colour.

Ammonia.-The chemical compofition of ammonia has been many years confidered as fully eftablihhed; but in the courfe of Mr Davy's experiments on the dccompofition of the fixed alkalies, it occurred to him that oxygen might alfo form one of the conftituents of ammonia, and this he alfo proved by experiment. Charcoal carefully burnt, and deprived of moillure, was ignited by a galvanic battery of 250 pairs of plates of fix and four inches fquare, in a fnall quantity of pure ammoniacal gas, confined over mercury. \(\Lambda\) grcat expanGon of the gafeous matter took place, and the white

\section*{Z I N}

Zinc. fubtance formed in the procefs colletted on the fides of the glafs tube. This matter effervefeed in diluted muriatic acid, fo that the product was probably carbonate of ammonia. A more decifive proof of ammonia containing oxygen as one of its elements, was obtained from another procefs. Very pure ammoniacal gas was paffed over iron wire ignited in a platina tube, and two curved glafs tubes were fo arranged as to be inferted into a freezing mixture, and through one of thefe tubes the gas entered into the platina tube, to be conveyed through it by the other glafs tube into an air-holder. The temperature of the air was \(55^{\circ}\), and no fenfible quantity of water was depofited in the cooled glafs tube, which tranfmitted the unchanged ammonia. But after being expofed to heat, moifture was very perceptible, and the gas appeared in the air-holder denfely clouded. This circumfance appeared to eftablifh the formation of the water from the decompofition of ammonia during the procefs. But after the gas had been paffed leveral times through the ignited tube, from one air-holder to the other, the iron wire was found fuperficially converted into oxide, and had increafed in weight Tid of a grain. About four-tenths of a grain of water were collected from the cooled glafs tubes by means of filtrating paper, and 33.8 cubic inches of gas were expanded into 55.3 cubic inches, and by detonation with oxygen it was found, that the hydrogen gas in thefe was to the nitrogen or azote as 3.2 to 1 in bulk.

Ammonia was farther fubjected to experiment by taking the electric fpark in it. In experiments of this kind it was underitood that it is refolved into hydrogen and azotic gafes; but Mr Davy found, after obferving feveral variations in the refults, that the weight of the two gafcs obtained was lefs by about one-eleventh than the weight of the ammonia employed. He afcribes this lofs to the oxygen of the alkali, which had probably combined with the wires of platina employed in the experiment, and had thus difappeared. From thefe experiments he eflimates the proportion of oxygen in ammonia at not lefs than 7 or 8 parts in 100 ; and as the gafes evolved may contain more water than the gas decompofed, the proportion may even be larger. By thus confidering ammonia as a triple compound of azote, hydrogen, and oxygen, the phenomena of its production and decompofition admit of an eafy explanation. In all cafes in which ammonia is formed, oxygen exifts along with its other elements, in the fubflances from the decompofition of which it is obtained. In the decompofition of ammonia, on the other hand, the oxygen, which forms one of its elements, may be abfracted by the fubltance employed in its decompofition, or it may enter into combination with portions of its hydrogen or azo'e.

But in the progrefs of invefligating the nature of ammonia, to which the attention of chemical philofophers has been particularly directed, it appears that this alkali is analogous to the fixed alkalies in having a metallic bafe. The Swedifh chemilts Rerzelius and Pontin, placed mercury negatively electrified in the galvanic circle, in contact with folution of ammonia. By this action the mercury increafed in volume, and aficr an expanfion of four or five times its former dimenfions, it hecame a foft folid. From this amalgam expofed to the air, mercury and ammonia are reproduced, with the abforption of oxygen; and when the amalgare is put

Vol. XX. Part II.
into water it forms ammonia, with the evolution of hydrogen, and the re-appearance of the mercury in its metallic ftate. Mr Davy repeated this experiment, and he found that to produce all amalgam, from 50 or 60 grains of mercury, in contact with a faturated folution of ammonia, required a confiderable time, and that this amalgam changed confiderably, even in the fiort pe. riod that was neceffary for removing it from the folu. tion. Concciving that the de-oxidation and combination with mercury might be more eafily tfected in its nafcent fate, he placed 50 grains of mercury in a cavity in muriate of ammonia. The muriate flighty moin= ened was placed on a plate of platina, and connected with the pofitive fide of a large galvanic battery. The mercury was made negative by means of a platina win; a frong effervefcence, with much heat, immediately look place; the globule of mercury in a few minutes enlarged to five times its former dimenfions. It had the appearance of amalgam of zinc. Netallic cryftallizations thot from it as a centre round the body of falt. They had an arborefcent appearance, often became coloured at their points of contact with the muriate, and when the conncetion was broken, rapidly difappeared, while ammoniacal fumes were given out, and the mercury was reproduced. With a piece of carbonate of ammonia, fimilar phenomena were exhibited. The amalgam was formed very rapidly; but when the galvanic action was powerful in this laft cafe, a black matter appeared in the cavity, which was probably carbone, from the decompofition of the carbonic acid.

Mr Davy confidering the ffrong attraction of potafo fium and fodium for oxygen, was led to examine whe. ther they produced any effect in the amalgamation of ammonia, independent of electricity. With this view he united fmall portions of potaflium and fodiurn with metcury, and brought them into contact with moiftened muriate of ammonia. An amalgam was formed, which rapidly increafed to fix or feven times its volume, and the compound feemed to contain a latger proportion of ammoniacal bafe than that obtained by electricity. It appears, too, that a portion of the metallic bafe employed to effect the de-oxidation always remained in combination with the compound, fo that it was not a pure am:lgam. The following are the properties of the amalgam from ammonia, obtained by means of galvanifm.

When this amalgam is formed at the temperature of \(70^{\circ}\) or \(80^{\circ}\), it is in the fate of a foft folid, of the confiftence of butter; at \(32^{\circ}\) it becomes firmer, and affumes a crytiallized form, in which fmall facets appear, which feem to be cubical. The amalgam of potallium cryftallizes in cubes, as beautiful, and in fome cafes as large, as thofe of bifmuth. The fpecific gravity of the amalgam is lefs than three, water being one. When the amalgam is ihrown into water, a quantity of hydrogen equal to half its bulk, is evoived, and the water be comes a weak folution of ammonia. The amalgam being confined in a given portion of air, the air increafes in bulk, and the mercury is revived. Ammoniacal gas equal to \(1 \frac{1}{4}\) or \(1 \frac{3}{3}\) ths of the volume of the amalo gam, is produced, and oxygen equal to one-feventh or one-eighth of the ammonia, difappears. When the amalgam is thrown into muriatic acid gas, it becomes inftantly coated with muriate of ammonia, and a fmall portion of hydrogen is evolved. In fulphuric acid it
becomes

Zinc. becomes coated with fulphate of ammonia and ful. phur.
Mr Davy attempted, by various methods, to preferve the amalgam, in the hope of fubmitting it to diltillation, for the purpofe of obtaining the metallic bafe of the ammonia, which was united to the mercury, in a feparate form. But as it is extremely difficult to free mercury, after being once moiftened entirely from water, he did not fucceed in this attempt. In wiping the amaigam carefully with bibulous paper, part of the ammonia was regenerated, and in paffing it through fine linen, with the view of feparating the moillure, a compiete decompofition was effected, and the mercury was revived.
The quantity of the bafe of ammonia combined with 60 grains of quickfilver, appears not to exceed \({ }^{\text {r }}\) o of a grain, and the quantity of oxygen required for this is not nove than \(\frac{\text { T }}{\text { TOOO }}\) of a grain of water, which might be fupplies by merely breathing upon the amalgam. Mr Davy made valious other experiments, with the view of afcertaining the nature and properties of the amalgam of ammonia; but for an account of thefe we mult refer to the paper itfelf. And he oblerves, that the more the fe properties are confidered, the more extraordinary will they appear. Mercury, by combination with about roloo of its weight of new matter, becomes folid, and yet has its fpecific gravity reduced from 13.5 to lefs than 3. retaining at the fame time its metallic characters, its co'our, luftre, opacity, and conducting powers, undiminilled. Can it then be conceived, Mr Davy afts, that a fubflance which forms with mercury fo perfect an amalgam, thould not be metallic in its own nature? This fubtlance he denominates ammonium. On what then, it is farther afked, do the metallic properties of ammonium depend ? Are hydrogen and nitrogen both metals in the gafeous flate, at the uftal temperature of the atmofihere; bodies of the fane character, as zine and mercury in the ftate of ignition? Os are thefe gafes in their common form oxides which becone metalized by de-oxidation? Or are they to be confidered as frunple bodies, not metallic in their own nature, but capable of compofing a metal when deprived of oxygen, and becoming an alkali with the addition of oxygen ?

In the farther profecution of the experiments relative to the nature of ammonia, Mr Divy employed potaffium. He brought ammonia into contact with about twice its weight of potaflum at common temperatures; but excepting a flight diminution in the volume of the gas, and the metal lofing its luftre and becoming white, no other effers were produced. The white crull when examined, proved to be potafh, and a fmall portion of hydrogen was found in the ammonia, but not more than equal in wolume to the metal. When the potaffium was heated in the gas, hy means of a firit lamp applied to the bottom of the retort, (fig. 5.) the eolour of the cruft change from white to bright azure, and grádually to bright bluc, green, and dark olive. The cruft and the metal then fufed together. This procefs is altended with effervefeence; and the cruft pafing off to the fides, exhitits the fhining furface of the potafium. When heated a ferond time, it fwells confiderably, becomes porous, cry hallizod, and of a beantiful zzure tint. A gas is evolved during this operation, which gives the fame dimisution bv detonation with oxygen, as hydrogen, and ammuria difappcars.

It has been obferved that the proportion of ammonia which lofes its elaftic form, varies according as the gas employed contains more or lefs moifure. Thus, in adsmonia faturated with water at \(63^{\circ}\) Falirenhcit, potafflum caufed the difappearance of twelve and a balf cubical inches of ammonia; but in ammonia deprived of moiflure, by expofure for two days to potafh that had been ignited, the fame quantity of potaflum occafioned the difappearance of 16 cubical inches; but whatever were the degrees of moilture of the gas, the quantity of hydrogen generated always appeared equal for equal quantitics of metal; and according to the Frenel chem:lls, the portions are flated to have been the fame as would have refulted from the action of water upon pota fium. But in Mr Davy's expcriments, the proportions were rather lefs. In one, conducted with great care, eight grains of potaffium generated, by their action upon water, eight and a half cubical inclies of hydrogen gas; and eight grains of potaflium from the fame mals, by their operation upon ammonia, produced \(8 \frac{7}{8}\) cubical inches of hydrogen gas. This difference, although inconfiderable, Mr Davy found always to take place.

In Mr Davy's experiments on the action of potaflium on ammonia, he employed retorts of plate glafs. The potaffium was faftened upon trays of platina or iron, which were introduced into the glafs retorts furninied with fop-cocks. The retorts were exhaufted by an airpump, then filled with hydrogen, exhaufted a fecond time, and afterwards filled with ammonia. (See fig. 5. Fig. Eo n. \(\%\) and 6.).
The following are the properties of the fubftance obtained from the action of ammonia on potaffum. 1. It is cryftallized, and prefents irregular facets, which are extremely dark, and in colour and luftre not unlike the green oxide of iron; it is opaque when examined in large maffes, but is femitranfpareat in thin films, and appears of a bright brown colour by tranfmitted light. 2. It is fufible at a heat a little above that of boiling water, and if heated much higher, emits globules of gas. \(\hat{3}\). It appears to be confidcrably heavier than water, for it finks rapidly in oil of faffafras. 4. It is a non-conductor of electricity. 5. When it is melted in oxygen gas, it burns with great vividnefs, emitting bright parks. Oxygen is abforbed, nitrogen is emitted, and potall, which from its great fufibility feems to contain water, is formed. 6. When brought into conta\& with water, it acts upon it with much energy, produces heat, and ofter inflammation, and evolves ammonia. When thrown upon water, it difappears with a hiffing noife, and globules from it often move in a flate of ignition upon the furface of the water. It rapidly effervefces and deliquefces in air, but can be preferved under naphtha, in which, however, it foftens flowly, and feems partially to diffolve. When it is plunged under water filling an inverted jar, by means of a proper tube, it inflantly difappears with effervefcence, and the non-abforbable elaffic fluid liberated is found to be hydrogen gas.

It is found that the weigltt of this fubflance is greater than that of the potaffium from which it is formed; and from this it is concluded, that part of the ammonia, or of its elements, enters into its compofition. When this fulftance is decompofed by heat, nitrogen and hydrogen gafes, with a portion of ammonia, are given out. It appears, howercr, that Lhe production of the ammonia
\(\underbrace{\text { Zinc. }}\) is in proportion to the moifture admitted, and when the moilture is confiderable, the whole product is ammonia. When this fubtance is expoled to heat, a matter remains, which even by increafing the heat, is no farther changed. On this reliduum water aels violently, and vilh elfervefcence, from the evolution of hydrogen gas. Ammonia and potafli are at the fame time reproduced. Mr Divy's conclufion from thefe experiments is, that the fubltance formed by the action of ammonia on potaflium is a compound of the latter with a fmall proportion of oxygen and nitrogen; and as it is found that the quantity of hydrogen given out during its formation is nearly equal to the hydrogen contained in the ammonia, it follows that neither hydrogen nor the ammonia itfelf can be fuppoled to enter into its compofi. tion.

In profecuting this invefligation, Mr Dary made various cxperiments, and whether the fubllance was acted on by water, expofed to the action of oxygen, or decompoled by heat, it was found, contrary to expectation, that the quantity of nitrogen evolved during its decompofition was much lefs than in proportion to the quantity of ammonia which had difappeared in its formation. In one experiment, in which the decompofition was effected by heat, the gafeous product was examined, an? was found to be partly potalh, and partly potafliom; but it afforded no traces of ammonia, when acted on by water, which is a proof that it retained no nitrogen. In another experiment, If cabic inches of ammonia, or 2.05 grains, were decompoled by potalium. The product was 3.6 cubic inches of nitrogen, equal to 1.06 grain; 16 cubic inches of hydroyen, equal to \(\cdot 382\) grain; and there was added to the potalfum a quantity of oxygen equal to .6 grain. Thefe products taken together amount to 2.04 grains, which is nearly equal to the quantity of ammonia employed; but this quantity of ammonia, if the proportions of its elements be eftimated, from its decompofition by electricity, would have yielded 5.5 cubic inches of nitrogen, equal to 1.6 grain, and only 14 cubic inches equal to .33 ; and allowing the feparation of oxygen in this procels in water, it cannot be eflimated at more than . 11 or .12 ; and hence, if the analy fis of ammonia by electicity come near to accurncy, there is in this procefs a confiderable lofs of nitrogen, and the production of oxygen and bydrogen.

How, fays Mr Davy, can thefe extraordinary refults be explained? The decompolition and compofition of nitrogen feem proved, and one of its elements appears to be oxygen; but what is the other element? Is the gas that appears to poflefs the properties of hydrogen a new fpecies of inflammable acriform fublance? Or has nitrogen a metallic bafis, which alloys with the iron or platina ? Or is water alike the ponderable matter of nitrogen, hydrogen, and oxygen? Or is nitrogen a compound of hydrogen, with a larger proportion of osygen than exifts in water ? Of thefe important queftions, Mr Davy adds, the two firft feem the leatt likely to be anfwered in the affirmative, from the correfpondence between the weight of the ammonia decompofed, and the products, fuppofing them to be known fubftances.

In concluding this \{ubject, we mut obferve, that it Aill remains in a confiderable degree of obfcurity. It feems, however, to be afcertained, that the bafe of ammonia is of a metallic nature, which muft be derived,
either from the nitroge: or the hydrogen, al from both, or perhaps thefe funtances are unly dift rent furas, of combination of the elementary bafe. Or if iutrogen le fuppofed to be an oxide of hydrogen, then hydugen in its galeous form is either a metallic fubilance, or has a metallic bafe, which latter enters iato combination with the mercary employed in the decampolition ot antuo. ma.

\section*{Decompafition of the Earlis.}

From the refults of the experiments on potaft and foda, waich Mr Davy obtained, he was led to entelam the itrongett lopes of being able to cifect the decurn ufitwo boin of the alkaline and common earths; and the phenomens which took place in the firll imperfect trials made opon thefe bodies countenanced the ideas, that had obtained fince the earlicit periudo of cisematry, if their being metallic in their nature.

The earths, like the fixed alkalies, are non-condactors of electricity; but the fiocd alkalies become conductors by fufion: the infufiole nature of the carths, however, rendered it impoffible to operate upon them in this Itate: the flrong affinity of their bafes for oxygen, made it unavailing, to act upon them in lolution in wa. ter; and the only methods that proved fuccefitul, were thofe of operating upon them by clectricity in fome of their combinations, or of combining them at the moment of their decompofition by electricity in metallic alloys, fo as to obtain evidence; of their nature and properties. 'Lo render the experiments upua the ear.hs fatislactory, a more pawerfol battery will be required, than Mr Davy has a profpee of feeing very foon conftructed; he therefore prefers the imputation of havine publithed unfinithed labours, to that oi having conceace; any new facts.

Parytes, ftrontites, and lime, fight!y moilened, were electrified by iron wires under naphtha, by the lame methods, and with the fame powers, as thofe empluved for the decompofition of the fixed alkalies. In thefe cafes gas was copioufly evolved, which was inilammable ; and the earths, where in contact with the negative metallic wires, became dark coloured and exhibited fmall points, having a metallic luftre, which, when cxpofed to air, gradually became white: they became white lifieufe when plunged under water; and when examined in this experiment with a magnifier, a agreenilh powder feemed to feparate from them, and fmall glooules of gas were difengaged.

In thefe experiments there was great reafon to believe that the earths had been decompofed; and that their bafes had combined with the iron, fo as to form alloys decompolable by the oxygen of the air or water; but the indiftinctnel's of the effect, and the complicated circum. Atances required for producing it, were fuch as to compel Mrr Davy to form other plans of operation.
M. Davy bearing in mind the ftrong attraction of potaffium for onygen, was induced to try whether this body might nol detach the oxygen from the earths, in . the fame manner as charcoal decompofes the common metallic oxides. He heated potaffum in contact with dry pure lime barytes, flrontites, and magnefia, in tubes of plate-glafs; but as he was obliged to ufe very fmal! quantities, and as he could not raife the heat to ignition without fufing the glafs, he obtained no good refults in this

7ine.

\section*{Z I N [796] Z I N}

Zinc. - manner." The potalfium appeared to ant upon the earths and on the glafs, and dark brown fubftances were obtain ed, which evolved gas from water ; but no diftinet metallic globules could be procured: from thefe, and other like circumftances, it feemed probable, that though potaffium may partially dcoxigenate the earths, yet its affinity for oxygen, at leaft at the temperature employed, is not fufficient to effeet their decompofition. Mr Davy, having made mixtures of dry potath in excefs and dry barytes, line, Atrontites, and magnefia, brought them into fufion, and acted upon them in the galvanic circuit in the fame manner as he employed for obtaining the metals of the alkalies. He expected that the potaffium and the metals of the earths might be deoxigenated at the fame time, and enter into combination in alloy.

In this way of operating, the refults were more difinct than in the laft: metallic fubftances appeared lefs fufible than potaffum, which burned the inftant after they had formed, and which by burning produced a mixture of potah and the earth employed. An attempt was made to form the metallic fubftances under naphtha, but without much fuccefs. To produce the refult at all, required a charge by the action of nitric acid, which the flate of the batteries would not often allow of; and the metal was generated only in very minute films, which could not be detached by fufion, and which were inftantly deftroyed by expofure to air.

Mr Davy had found in his refearches upon potaflium, that when a mixture of potain and the oxide of mercury, tin, or lead, was eleetrified in the galvanic circuit, the decompofition was very rapid, and an amalgam, or an alloy of potaffium, was obtained; the attraction between the common metals and potaflum apparently accelerating the feparation of the oxygen. The idea that a fimilar lind of action might affift the decompofition of the alkaline earths, induced him to electrify mixtures of the fe bodies and the oxide of tin, of iron, of lead, of filver, and of mercury; and thefe operations were far more fatisfactory than any of the others.

A misture of two-thirds of barytes, and one-third of oxide of filver very flightly moiftened, was electrified by iron wires; an effervefcence took place at both points of contact, and a minute quantity of a fubfance, polieffing the whitenefs of filver, formed at the negative point. When the iron wire to which this fubflance adhered, was plunged into water containing a little alum in folution, gas was difengaged, which proved to be hydrogen; and white clouds, which were found to be fulphate of barytes, defcended from the point of the wire.

A mixture of barytes and red oxide of mercury, in the fame proportions, was electrified in the fame manner. A fnall mafs of folid amakgam adhered to the negative wire, which evidently contained a fubfance, that produced barytes by expofure to the air, with the abforption of oxygen; and which occafioned the evolution of hydrogen from water, leaving pure mercury, and producing a folution of barytes.

Inlixtures of lime,' frontites, magnefia, and red oxide of morcury, treated in the fame manner, gave fimilar amalgams, from. which the alkaline earths were regener: ated by the action of air or water, with like phenomena; but the quantities of metallic fubfances obtained were exceedingly minute ; they appeared as mere fuperScial formations furrounding the point of the wire, nor did they increafe after the firt few minutes of electriza-
tion, even when the procefs was carried on for fome hours.

Thele experiments were at firf made when the batteries were in bad order; but were afterwards refumed with a new and much more powerful apparatus, confructed in the laboratory of the Royal Intitution, and condifting of five hundied pairs of double plates of fix inches fquare.

When Mr Davy attempted to obtain amalgams with this apparatus, the tranfmitting wires being of platina, of about \(z^{\frac{y}{\delta}}\) of an inch diameter, the heat generated was fo great as to burn both the mercury and bafis of the amalgam at the moment of its formation; and when, by exiending the furfaces of the conductors, this power of ignition was modified, yet ftill the amalgam was only procured in thin films, and globules fufficiently large to fubmit to diftillation could not be procured. When the trarfmitting wires were of iron of the fame thicknefs, the iron acquired the temperature of ignition, and combined with the bafes of the earths in preference to the mercury; and metallic alloys of a dark grey colour were obtained, which acted on water with the evolution of hydrogen, and were converted into oxide of iron and alkaline earths.

While Mr Davy was engaged in thefe experiments, he received a letter from Profeffor Berzelius of Stockholm, who ftated that in conjunction with Dr Pontin, he had fucceeded in decompofing barytes and lime, by negatively electrifying mercury in contact with them, and that in this way he had obtained amalgams of the metals of thefe earths.

Mr Davy immediately repeated thefe operations with perfect fuccefs; a globule of mercury, electrified by the power of the battery of 500 , weakly charged, was made to act upon a furface of flightly moiftened barytes, fixed upon a plate of platina. The mercury gradually became lefs fluid, and after a few minutes was found covered with a white film of barytes, and when the amalgam was thrown into water, hydrogen was difengaged, the mercury remained free, and a folution of barytes was formed.

The refult with lime, as thefe gentlemen had fated, was precifely analogous. Strontites and magnefia were decompofed in the fame manner.

From frontites the expected refult foon took place; but from magnefia, in the firt trials, no amalgam could be procured. By continuing the procefs, however, for a longer time, and keeping the earth continually moif, at laft a combination of the bafis with mercury was obtained, which flowly produced magnefia by abforbing oxygen from the air, or by the action of water.

Mr Davy found that all thefe amalgams might be preferved for a confiderable period under naphtba. In length of time, however, they became covered with a white cruft under this fluid. In water, the amalgam of barytes was moft rapidly decompofed; that of frontites and that of lime next in order : but the amalgam from magnefia, as might be expected fiom the weak affinity of the earth for water, very flowly changed. When a little fulphuric acid was added to the water, however, the evolution of hydrogen, and the production and folution of magnefia, were exceedingly rapid, and the mer. cury foon remained free.

Mr Davy believed, that one reafon why magnefia: was lefs eafy to metallize, than the other alkaline earthis.

\section*{Z• \({ }^{7} \mathrm{~N}\)}

Zinowes was owing to its infolubility in water, which would prevent it from being prefented in the nafeent ftate, detached from its folution at the negative furface.

He then made the experiment, ufing moiltened fulphate of magnefia inftead of the pure earth; and the amalgan was much fooner obtained. Here the magnefla was attracted from the fulphuric acid, and probably deoxigenated and combined with the quickfilver at the fame inttant. "1.

The amal gams of the other bafes of the alkaline carths could be obtained in the fame manner from their faline compounds: muriate and fulphate of lime, the muriate of ftrontites and barytes, and nitrate of barytes, were decompoied by the fame means as the other eartlis. The earths, leparated at the deoxigenating furface, thefe feemed inftantly to undergo decompofition, and, feized upon by the mercury, were in fome meafure defended from the action of air, and from the contact of water, and preferved by their ftrong attraction for this metal.

In attempting to procure the metals of the alkaline earths, the latter were flightly moiltened, and mixed with one-third of red oxide of mercury ; the mixture was placed on a plate of platina; a cavity was made in the upper part of it to receive a globule of mercury, of from 50 to 60 grains in weight; the whole was covered by a film of naphtha, and the plate was made pofitive, and the mercury negative, by a proper communication with the battery of five hundred.

The amalgams obtained in this way were diftilled in tubes of plate-glafs, or in fome ca?es in tubes of common glafs. Thefe tubes were bent in the middle, and the extremities were enlarged and rendered globular by blowing, fo as to ferve the purpofes of a retort and receiver. The tube, after the amalgam had been introduced, was filled with naphtha, which was afterwards expelled, by boiling, through a fmall orifice in the end correfponding to the receiver, which was hermetically fealed when the tube contained nothing but the vapour of naphtha, and the amalgam. It was found immediately that the mercury rofe pure by difillation from the amalgam, and it was very ealy to leparate a part of it; but to produce a complete decompofition was very difficult, as nearly a red heat was required for the purpofe, and as at a red heat the bafes of the earths inftantly acted upon the glafs, and became oxigenated. When the tube was large in proportion to the quantity of amalgam uled, the vapour of the naphtha furnihhed oxygen fufficient to deftroy part of the bafes: and when a frmall tube was emploved, it was difficult to heat the part ufed as a setort fufficient to drive off the whole of the mercury from the bafes, without raifing too highly the temperature of the part ferving for the receiver, fo as to burlt the tube.

In confequence of thefe difficulties, in a multitude of trials, only a very few fuccef,ful refults were obtained; and in no cafe could our author be abfolutely certain, that there was not a minute portion of mercury fill in combination with the metals of the earths.

In the beft refult obtained from the dinillation of the amalgam of barytes, the refiduum appeared as a white metal, of the colour of filver. - It was fixed at all common temperatures, but became fluid at a heat below rednefs; and did not rife in: vapour when heated to rednefs, in a tube of plate-glafs, but anted violently up-

\section*{797 ] Z I N}
on the glafs, producing a black mats, which feemed to contain barytes, and a fixed alkaline bafis, in the firft degree of oxigenation. When expoled to air, it rapidly tarnillsed, and fell into a white powder, which was barytes. When this procefs was conducted in a fmall portion of air, the oxyren was abrorbed and the nitrogen remained unalsered; when a portion of it was introduced into water, it acled upon it with great volence and funk to the bottom, producing in it barytes ; and hydrogen was generated. From the minutenels of the quantities obtained, neither its phyfical nor chemical qua. lities could be examined correctly. It funk rapidly in water, and even in fulphuric acid, though furrounded by globules of hydrogen, equal to two or three times its volume; from which it fcems probable, that it cannot be lefs than four or five times as heavy as water. It flattened by preflure, but required a confiderable force to produce this cffect.

The metal from frontites funk in fulphuric acid, and exhibited the fame characters as that from barytes, except in producing ftrontites by oxidation.

The metal from lime, Mr Davy has never been able to examine, either when expofed to air, or when under naphtha. In the cafe in which he was able to diftil the quickfilver from it to the greateft extent, the tube unfortunately broke, while warm, and at the moment that the air entered, the metal, which had the colour and luftre of filver, inftantly took fire, and burned with an intenfe white light into quicklime.

The metal from magnefia feemed to aft upon the glafs, even before the whole of the quickfilver was difilled from it. In an experiment in which the procefs was ftopped before the mercury was entirely driven off, it appeared as a folid; having the fame whitencls and luftre as the metals of the other earths. It funk rapidly in water, though furrounded by globules of gas producing magnefia, and quickly changed in air, becoming covered with a white cruft, and falling into a fine powder, which prored to be magnefia.

In feveral cafes in which amalgams of the metals were obtained, containing only a fmall quantity of mercury, they were expofed to air on a delicate balance, and it was always found, that, during the converfion of metal into earth, there was a confiderable increase of weight.

Mr Davy endeavoured to afcertain the proportions of oxygen and bafis in barytes and ftrontites, by heating amalgams of them in tubes filled with oxygen, but without fuccefs. He fatisfied himfelf, however, that when the metals of the earths were burned in a fmall quantity of air, they abforbed oxygen, gained weight in the procefs, and were in the highly cauttic or unflaked flate; for they produced flrong heat by the contact of water, and did not effervefce during their folution in acids.

The evidence for the compoftion of the alkaline earths is then of the fame kind as that for the comportion of the common metallic oxides; and the principles of their decompofition are precifely fimilar, the inflammable matters in all cales feparating at the negative furface in the galvanic circuit, and the oxygen at the pofitive furface.

Mr Davy has denominated the metals obtained from the alkaline earths, barium, frontium, calcium, and mag. num.

In attempting the decompofition of the otber earthes,
315

\section*{Z. I N \\ 8 ] Z, I N}

Mr Davy was lefs fortunate in obtaining diftinet refults; and he oblerves that the methods which have whilually proved fuccerfful, as well' as fome others, failed. When alumina was fubjected to the action of elcetricity, it was in a flate of fufion with potafh. In this procels metallic globules were produced, but they coufited chietly of the bale of the alkali. Some appearances, however, flewed, that the alumina itfelf was decompofed; for when foda was employed, the metallic product obtained was lefs fufible than fidium iifelf, and when it was acted on by water, it produced foda and a white powder. When potah was fufed with the alum:na, and fubjected to galvanic action, the metallic prodith decompoled water with great rapidity, and the folution obiained depcfi ed alumina by the action of an acirl. When potafium in the ftate of amalgam, with one third of merrury, in contact with alumina, was negatively electrifed under naphtha, and after the procefs had been continued for fome time, the amalgam was added to water, a decompofition took place, and a folution was obtained, which produced a cloudinefs on the addition of an acid ; but all thefe refults are to be confitered as very imporfect evidence of the decompofition of alumina.

Mr Davy was fill lefs fuccefiful in attempting the decompofition of filica, pattly from its infolubility, and partly from its being fcarcely, if at all, affeled with electricity, when diffufed in water, and placed in the galranic circuit ; but by following the fame procefles as in his experiments on alumina, fome indications of decompofition appeared. When filica was fufed with fix parts of potah, and was placed in fufion in the galvanic circuit, metallic matter was obtained, from which, by expofure to the air, or by dropping it into water, a minute quantity of filica was reproduced. When potaffium, a malgamated swith one-third of metcury, and in contact \(\therefore\) is filica, was negatively electrified, he obtained a fir milar refult; but in none of the experiments could the product obtained be confidered as the pure bafe of the earth.

The earths of zirconia and glucina were alfo fubjected to the action of galvanifm, by proceffes finila: to thofe which have now been defribed, and in both there were fome indications of decompofition; but the refults were not fo perfect as to lead to any certain conclufion refpecting their nature.

\section*{Decompofition of Sulphur and Phofphorus.}

Sulphur.-Sulphur, which had formerly been confidered as a finple fubftance, appears, from the experinients of frme of the French chemifts, and particularly thofe of Perthollet junior, to be a compound of fulphur and hydrogen. The latter chemift, in his experiments to inveftigate the nature of this fubrance, caufed fulphur to pafs througlo a coated glafs tuhe, which was heated to whitenefs; fome indications of fulphurated hydrogen were obtained. He theri formed metallic fulphurets, as of iron, copper, and mercury, and in thefe proceffes, which were performed in an earthen retort with great care, fulphurated hydroyen gas was alfo obtained. Water in the fate of vapour being paffed over fulplaur in fuifon, caufed the evolution of fulphurated hydrogen; the water was not decompofed, for no trare of acid could be obferved. It feemed only to have effected the difengagement of hydiogen from the lilphur.

Mr Davy, in the courfe of his experiments in galvan-
in, fubjected fulpher to the action of that power. The fulphur which lise employed was fublimed in a retort, filld with azotic gas, and it was kept hat till the com. mencement of the experiment. The realon of this preliminary procefs was, to avoid any uncertainty which might arife from water abforbed by the fulphur. The fulplupr introduced into a curved tube, fig. 7. Which was furaifted with wires of platina \(A\) and \(B\), the upper wite A being hermetically fealed into the end of the tube, was the:a placed in the galvanic circuit of a battery of 500 pairs of plates of fix inches, in a tate of great activity. A very intenfe action follorved, accompanied by great lieat and a brilliant light. The fulphur foon entered into ebuilition, and gave out a great quantily of elaftic fluid, a good deal of which was permainent. The fulphur itfelf aftumed a deep red brown colour. The gas obtained was fulphurated hydrogen. In another experiment made on200 grains of fulphur, the amount of fulphurated hydrogen obtained was equal to more than five times the volume of the fulphur. A confiderable action was obferved to have taken place on the wires of platina; and the fulplur, at its point of contact with the wires, reddened moif litmus paper. When fulphur and potaffum are heated together, a very powerful action takes place. Sulpt: \(\omega\) ated hydrogen is difengaged with very intenfe heat and light. From thefe experiments the conclufion feems fair and obvious, that hydrogen exifts in fulphur, for a fubfance, as Mr Davy obterves, which can be produced from it in fuch abundance, is not to be confidered mereiy as an accidental ingredient.

But as it is admitted that fulphurated bydrogen con. tains oxygen, Mr Dary contends that axygen is to be regarded as one of the conffituents of fulphur. In this opinion he is fupported by experiment. He heated potaffium in fulplurated hydrogen gas, from which noilture had been as much as pofible abiliacted, by muriate of lime. The potaflum took, fire, and burnt with a brilliant flame. When four grains of potaffium were beated in 20 cubic inches of gas, the quantity of gas diminimed only about \(2 \frac{1}{2}\) cubic inches; hut the properties of the gas were totally changed. A fmall portion only of it was abforbed by water, and the remainder was hydrogen, holding in folution a minute portion of fulphur. Some fulphur was obferved on the fides of the retort, and a folid matter was formed, which on the fur race was of a red colour, like fulphuret of potafh, but internally dark gray, like fulphuret of potalliums. By fubjecting this fubflance to the action of muriatic acid, fulphurated hydrogen gas was obtained, but the proportion was lefs than would have been given out, had the potafium been in combination with pure combuftible matter. From this Mr Davy concludes, that there is a principle in fulphurated hydrogen which is capable of defroying parLially the i, fimmability of potiffium, and of producing upon it all the effects of oxygen. As fulphurated bydrogen is obtained by heating fulphur flrongly in hydrogen gas, Mr Davy introduced four grains of fulphur in a glafs retort, containing about 20 cubical inches of hydrogen, and by means of a fyirit lamp, lie raifed the hea: nearly to rednefs. No perceptible change took place in the volume of the gas after the procefs. The fuhlin ed fill hur was unchanged in its properties, and ahout three cubical inches of unelaftic fuid, abforlable by water, \(r\) ddening limus, and having all the properties of fulphurated bydrogen gas, were formed. Suppofing then
fulphurated fulphurated lydrogen to be conftituted by fulphur diffulved in its uachanged fate in lydrogen, and admit the cxiltence of oxygen in this gas, its exiftence nult likcwife be allowed in fulplur. From thele experiments Mr Davy thinks it not unreatonable to affume, that fulphur in its common tate is a compound of fmall quanlities of oxygen and lyydroren, with a large quantily of a bafe, which produces the acids of fulphur in combuf. tion; and as this bafis, it is added, poliefles flrong at. tractions for other bodies, it will probably be very diflicult to obtain it in its uncombined fate.

Sulphui combincs readily with potallium, when bruisht inso contact in tubes filled with the valume of naphtha; heat and light are sapidly evolved during the combination, and a gray fubitance like arlificial fulphuret of iron, is produced. Ine fulphurated hydrosen in finall quantity is formed at the moment of combination, the hydroges of which, it is fuppofed, is derived from the fulphur. The fulphuret of potallium readily inflames, and when expofed to the air, it is gradually oxidated, and converted into fulphate of potall.

Sulphur alfo enters into combination with lodium, accompanied alfo with the cvolution of heat and light. An explofion fometimes takes place, which is owing to the volatilization of a portion of lulphur, and the difengagement of fulphurated hydrogen gas. The fulphuret of fodium is of a dcep gray colour.

Phofpho:us.-Mr Davy fubjected phofphorus to fimilar experiments, and he found that the fame analogies are applicable to this combullible. Common electrical fparks tranlinitted through phofphorus produce no cvolution of permanent gas; but when afted upon by the fame galvanic battery, and in the lame circumfances as the fulphur, a confiderable evolution of gas was effected, and the pholphorus became of a deep red brown colour. The gas was phofphorated hydrogen; and in an experiment continued for fome hours, the quantity evolved was four times the volume of the phofphorus. The light by the galvanic fpark was at firt a brilliant yellow, and afterwards orange.

Three grains of potaffum were heated in 16 cubical inches of phofyhorated hydrogen. A: the fufion was effected, the retort was flled with white fumes, and a reddill fuhfance was depofited upon the upper part and fides; the heat was applied for fome minutes, but no inAammation took place. When the retort cooled, the abforption was lefs than a cubical inch; the potallium externa:ly was of a deep brown, and internally of a lead colour. The refidual gras feemed to contain in folution a little phophorus, but it had not the property of fan. taneous inflammation. While the phofphuret was acted upon over mercury by a folution of muriatic acid, it gave out only \(1 \frac{3}{4}\) cubical inch of phofphorated hydrogen.

One grain of potaffum, and one of phofhorus, were fufed together. In combining, a very vivid light and intenfe ignition were produced; \(\frac{1}{15}\) of a cubical inch of phopphorated hydrogen was evolved, and the phofphuret, with diluted muriatic acid over mercury, gave out r \(^{3} 0\) of a cubical inch of phofphorated hydrogen. In another experiment with one grain of potaflium, and three of phofphorus, nearly one-fourth of a cubical inch of phofphorated hydrogen was obtained; but the compound yiclded by muriatic acid, only \(\frac{1}{10}\) of a cubical inch.
lirnm thefe experiments it is concluded, that phof= plarated bydrogen contains a minute proportica of oxy-
gen, and confeguently that the fame elemen: cnters into the compofition of pholphorus. 'The deficiency of ", hof

Zinc. phorated hydrogen in thie laft experiment can only be referred to the lupply of oxygen to the putallium from the pholphorus; and the quantity of phofphorated hydrogren produced ul the experiment with equal parts of potaflium and phoiphorus, is much lefs than could be expeeted, if the potailium and phofphorus confited mersly of pure combutible matter.

Mr Davy allo inilituted a fet of interening experiments on the fates of the carbonaceous principle in plumbago, charcoal, and the diamnend, and the refilts of thefe are detailed in the fame memoir; but for a:l as count of them we mult refer to the paper itfelf.

\section*{- Decompfrion of Boracic, Fluoric, and Muriatic acids.}

The properites of boracic, tluoric, and muriatic acids, many of which are puite analogous to thofe of other acids whofe clements lave been difoovered, lave led chemitts to conclude that oxygen is alfo the acidifying principle in the former; but the feparate exiftence or nature of the bafe of thefe three acids was, till the late refearches of galvanifin were inftituted, utterly unknown. The inveligation of the nature of thefe fubllances has been profecuted by Mr Divy, and fone of the Frencla chemilts; and of their experiments we lhall now give a very thort account.

Boracic acid.-When boracic acid was moiftened with water, and expufed between twa furfaces of platina, and then fubjected to the battery of 500 plates, an olive brown matter formed on the negative furface, and, increafing in thicknefs, appeared at laf. almoft black. This fubftance was permanent in water, but it diffolved and effervefeed in warm nitrous acid. Heated to rednefs on the platina, it burnt flowly, and gave off white fumes, which reddened moiltened litmus paper. A black mats remained, which through a magnifier appeared vitreous, and feemed to contain a fixed acid. The inference drawn from this experiment is, that the acid was decompofed, and again by the latter procefs reproduced.

When equal weights of potafium and boracic acid were heated together in a green glafs tube, which had bsen exhaufted, after being twice fileed with hydrogen gas, an intenfe ignision, with vivid infammation, where the potafium was in conta\{ with the boracic acid, took place, even before the temperature approached near to a red heat. When the acid had heen heated to whitenefs, before being introduced into the tube, and pawdered and ufed while yet warm, the quantity of gas which was hydrogen, given out in the operation, did not exceed twice the volume of the acid. In this mode of condueting the experiment, 12 or 14 grains of each of the two fubtances only could be einployed, on account of the intenfe heat and confequent fufion of the glafs tube with larger proportions. Mr Divy found in feveral experiments, in which he employed equal parts of acid and potaffium, that a great proportion of the former remained undecompufed, and he afcertained that twenty grains of poiaflium had their inflammability deftroyed by eight grains of boracic acid.

To colled the fubftances formed in the procels, me. tallic tubes with fop-cocks, and exhaufted, after being flled with bydrogen, were employed. With tubes of brafs or copper, a dull red heat only, but with iron

\section*{Z I N [ 800 ] Z I N}
tubes, a white heat was applied; and in all cafes the acid was decompoled with the fame refults. The fubflance obtained from the inon tube was in fome parts of a dark olive colour, and in others almoft black. It did not effervefce with warm water, but was rapidly acted upon by it. The folutions obtained confffed of fubborate of potafn, and potah.

The following are the properties of the fubftance obtained in the decompofition of boracic acid by means of proceffes conducted in brafs tubes, which afforded it in largeft proportion. To this fubftance Mr Davy has given the name of boracium, which, as it is produced in the manner now defcribed, is in the form of a pulverulent mafs of the darkeft thades of olive; it is opaque, very friable ; the powder does not fcratch glafs, and is a non-conductor of electricity. Dried at \(100^{\circ}\) or \(120^{\circ}\), it gives off moifture, by decreafing the temperature; and when heated in the atmofphere, takes fire at a temperature below the boiling point of olive oil, emitting a red light, and faarks like charcoal. When excluded from air, and fubjected to a white heat in a platina tube, exhaufted after being filled with hydrogen, it remains unchanged, excepting in becoming a little darker, and acquiring a greater fpecific gravity.

Boracium introduced into a retort filled with oxygen gas, and heated by a fpirit lamp, throws off vivid fcintillations like thofe of the combuttion of the bark of charcoal, and the mals gives out a brilliant light. A fublimate appears, which is boracic acid; it becomes coated with a ritreous fubftance, which is allo found to be the fame acid. When this is wafhed off, the black refiduum requires a greater heat, but it is alfo inflamed, and converted into boracic acid. When boracium is brought into contact with oxymuriatic acid gas, at common temperatures, it immediately takes fire, and burns with a brilliant white light, coating the infide of the veffel with a white fubflance, which is boracic acid. Boracium heated to rednefs with hydrogen or nitrogen, became of a darker colour, and gave out a little moifture, but remained otherwife unchanged. Thrown into concentrated nitric acid, it rendered it bright red; nitrous gas was produced and abforbed, but no rapid folution took place till the acid was heated, when the boracium difappeared with effervefcence, and the evolution of nitrous gas, and the fluid yielded boracic acid. The action of boracium on fulphuric and muriatic acids was not remarkable. It combined with the fixed alkalies, both by fufion and aqueous folution, and formed pale olive-coloured compounds, which by muriatic acid were precipitated of a dark colour. When fuled with fulphur, it diffolved flowly, and the fulphur became of an olive colour. Its attion with phofphorus in the fame circumftances was ftill feebler, but it communicated a thade of pale green.

From the experiments now detailed, it appears that boracium obtained by means of potaflium, is different from any other known feecies of matter, and feems to be the fame as that obtained from boracic acid by electricity. According to the refult of experiments made by Mr Davy, boracic actd is compofed of one part of boracium, and about 1.8 of oxygen; and fuppofing the dark refidual fubtance to be an oxide, it confifts of 4.7 of boracium, and 1.55 of oxygen.

For an account of the experiments of Gay Iuffac and Thenard, in inveltigating the nature of boracic acid,
fee Joul. de Phyfique, tom. Ixvii, or Nichol. Jour. xxiii. 260.

Fhuoric acid.-According to the experiments of Mr Divy, potaflium, when heated in Huoric acid gas, undergoes combultion, and a great ablorption of the gas takes place. In other experiments he found, that when fluoric acid gas, procured in contact with glafs, is introduced into a plate glafs retort, exhaufted after being filled with hydrogen gas, white fumes appear from the action of the potaflium, which lofes its fplendour, and becomes coloured with a gray crult. The fumes are more copious when the bottom of the retort is gently heated. The volume of the gas examined at this time appears to be a little increafed, with the addition of hydrogen; and when the temperature is raifed nearly to the point of fublimation of the potafium, the metal rifes through the crult, becomes firft of a copper colour, and then inflames and burns with a brilliant red light. After this combuftion, the fluoric acid is cither wholly or partially deftroyed, according as the quautity of potaffum is great or fmall; and a mafs of a chocolate colour is found in the bottom of the retort ; the fides and the top are lined with a fublimate, which is partly chocolate, and partly of a yellow colour. When the refidual gas is walhed with water, mixed with oxygen gas, and expofed to the action of an electrical fpark, it detonates, and affords a diminution in the fame way as hydrogen gas.

In one experiment with ig cubical inches of fluoric acid gas, and ten grains and a half of potaffum, \(14 \mathrm{cu}-\) bical inches of the gas difappeared, and about two and a quarter of hydrogen gas were produced. The gas had not been artificially dried; little fublimate was produced, but the whole of the bottom of the retort was covered with a brown crt:ft. When this mafs was examined with a magnifier, it feemed to confift of different kinds of matter. It did not conduct electricity ; it effervefced violently.in watcr, with the evolution of an inflammable gas, which had fomewhat of the odour of pholphorated hydrogen. Part of the mals heated in the air burnt flowly, and was converted into a white faline matter. It alfo burnt with difficulty in heated oxygen gas, but it abforbed a portion that required nearly a red heat. The light emitted refembled that from the combuftion of liver of fulphur. Chocolate coloured particles were found floating in the water, acted on by a portion of the mals, and when the folid matter was feparated by the filter, the fluid was found to contain fluate of potalh and potafh. The folid refiduum was heated in a fmall glals retort filled with oxygen gas; it burnt before reaching a red heat, and became white. Oxygen was ablorbed, and acid matter produced. The remainder had the properties of the fubfance formed from fluoric acid gas, holding fliceous earth in folution by the action of water.
"The decompofition of the fluoric acid, Mr Davy obferves, by potaftum, feems analogous to that of the acids of fulphur and phofphorus. In neither of thefe cales are the pure bafes, or even the bales in their common form, evolved; but new compounds refult, and in one cafe, fulphurets and fulphites, and in the other phorphurets and phofphites of potafh, are generated."

In another experiment Mr Davy attempted the niecompofition of tuoric acid gas, which was perfectly dry, and free from filiceous earth, by mixing 100 grs .
of dry boracic acid, and 200 grains of fluor fyar. The mixture was introduced into the bottom of an iron tube, having a ftop-cock and tube of fafety attached. The tube was inferted horizontally in a furge, and 20 grains of potaffum in an iron tray were placed in that part of it where the heat was only of a dull red. The bottom of the tube was raifed to a white heat, and the acid, as it was generated, was acted upon by the heated potaf. fium. The refult obtained was a fubftance in lome parts black, and in others of a dark brown coluur. It did not effervefce with water, and when lixiviated, afforded a dark brown combuftible mafs which did not conduet eleetricity, and, when burnt in oxygen gas, afforded boracic and fluoric acids. This fubltance did not inflame fpontaneoufly in oxymuriatic acid gas; but it effervefced violently, and diffolved in nitric acid. Mr Davy thinks that this fubflance is a compound of the olive-coloured oxide of boracium, and an oxide of the bafe of Auoric acid; but he bad not examined its properties particu. larly.

Muriatic acid.-Many conjectures have been offered with regard to the nature and conftitution of muriatic acid, and many attempts have been made to effect its decompofition. Mr Davy has extended his refearches to this fubttance, and has profecuted the inveltigation with his ufual ardour. It is flll, however, to be regretted, that his fuccefs has not been commenfurate with bis ingenuity and induftry. Some have fuppofed, that the bafe of muriatic acid is hydrogen, while others contend that the bafe is a compound of hydrogen and nitrogen.

The refult of Mr Davy's firlt experiments in this inquiry thowed, that the water alone in combination with the muriatic acid is decompoled, and that this elaftic fluid contains a larger proportion of water than is ufually fufpected; and from various experiments he concludes, that muriatic acid gas, in its common ftate, is combined with at leaft one-third of its weight of water. In the profecution of his refearches, therefure, his object was to obtain the muriatic acid free from water. With this view he beated dry muriate of lime, mixed both with phofphoric acid, and dry boracic acid, in tubes of porcelain and of iron, and employed the blaft of an excellent forge; but by none of thefe methods was any gas obtained, till a little moifture was added to the mixture, and then muriatic acid was given out in fuch quantity as almolt to produce explofions. In diftilling the liquor of Libavius, or the fuming muriate of tin, which contains dry muriatic acid, with fuiphur and with phofphorus, no feparation of the acid took place; but with the addition of water, muriatic acid gas was evolved with great heat and violence. By diftilling mixtures of corrofive fublimate and fulphur, and of calomel and fulphur in their common ftates, muriatic acid gas was evolved; but when thefe fubftances were dried by a gentle heat, the quantity of gas obtained was greatly diminifhed. Mr Davy, and alfo the French chemifts, endeavoured to procure diy muiatic acid by the difillation of a mixture of calomel and phofphorus. The refult obtained is confidered as a compound of muriatic acid, phofphorus, and oxygen. In Mr Davy's experiments, the product was more copious when corrofive fublimate was employed. With the fame view of procuring dry muriatic acid gas, he expoled phufphorus to the action of oxymuriatic acid gas, in the hope

Vol.. XX. Part II.

\section*{1 Z I N}
that in the oxidation of the phofplorus, the whole of the moillure would be abforbed; but the examination of the reflult flowed, that no muriatic acid gas had been cvolved during the procefls, fo that the inuriatic acid which had diappeared, mult cxift, either in the white fublimate which had colleeted in the top of the retort, 'or in a limplid tluid which had formed in its neck. When the fublimate was expofed to the air, it emitted funes of muriatic acid, and when brought into contact with water, muriatic acid gas was evolved, and phofphoric and ruuriatic acids remained in foiution in the water. Mr Divy regaids this white fublimate as a combination of photphoric and muriatic acids in their dry fates. The limpid fuid was of a pale greemfla yellow colour ; it rapidly difappeared on exprolure to the air, emitting denfe wlite furres, which had a itrong fmell, differing a lietle from that of muriatic acid. Mr Davy thinks that this is a com pound of phofphuric and muriatic acids, both fiee from water.
Mr Davy made other experiments, for the purpofe of procuring muriatic acid in its uncombined fate, but with no better fuccefs. He then tried the effects of potaffium introduced into the fluid gencrated by the action of phofiphorus on corrofive fublitirate; but fuch was the vilulent actiun of the fubflances opcrated upon, that the apparatus was generally deffroycd, and he was thus precluied from examining the retults. But for a particular detail of the experiments, we mull rcfer to the memorr itielf; and for the extended account of Mr: Davy's invelfisations on this curius and interelting fubjeet, of which we have given as comprehenfive a vicw as our limits would permit, fee Pail. Tranf. 1807. 1808, and 1809.

ZINNIA, a genus of plants of the clafs fyngencia, and in the natural tyftem arranged under the 49 th order, Compofite. See Botanv Indix.
ZinZendorff, Nicholas Lewis, Coust, was the noted founder of the German religious fect called Moravians, or Herrnhuters, or, as they pretend, the reftorer of that fociety. From his own narrative it appears, that when he came of age in 1721 , his thoughts were wholly bent on gathering togetlier a litule fociety of believers, among whom he might live, and who fhould entirely employ themiflues in exerciles of devotion under him. He accordingly purchafed an effate at Bertholidorff in Upper Lufatia, where, being joined by fome followers, he gave the curacy of the village to a perfon of his own complexion; and Bertholfdorff foon beesme talked of for a new mode of piety. One Chrilitian David, a carpenter, brought a few profelytes from Moravia : they began a new town about half a league from the village, where Count Zinzendorff fixed his refidence among them, and whither great rumbers of Moravins focked and eflablifled themiclves under his protetion : fo that in 1732 their number amounted to 600 . An adjacent hill, called the Huthberg, gave arcafion to thefe colonifts to call their new fettlensent Huth des Herrn, and afierwards Herrnluth; which may be interpreted "The guard or proieftion of the Lord:" and from this the whole fef have taken their name. The couns fpared neither pains ror art to propazate his opinions ; he went himfelf all over Europe, and at icaft twice to America; and fent miffionaries throughout the worlll. Count Zinzerdorfi died in \(1 ; 60\). Thiofe who will to know more of the Morayian tenets may confalt Rimius's
account of them, tranflated in 1753. See United Bretilrkn.

ZISCA, Jонn, a famous general of the forces of the Huffites, in the 15 th century, was a gentleman cducated at the court of Bohemia, in the reign of Wenceflaus. He entered very young into the army, and after diffinguining himfelf on feveral occafions, lon an eye in a battle, whence he was called Zifea, or One-eyed. At length the Reformation, begun by John Hufs, fpreading thro;gh almoft all Bohemia, Zifca placed himfelf at the head of the Huflites, and had foon under his command a body of 40,000 men. With this anmy he gained feveral vifories over thofe of the liomilh religion, who carried on a kind of crufade againी them, and built a town in an advantageous fituation, to which he gave the name of Tabor; whence the Huffites were afterwards called Taborites. Zifca lof his other eye by an arrow at the fiege of the city of Rubi; but this did not prevent his continuing the war, his fighting battles, and gaining feveral great victories, among which was that of Aufig on the Elbe, in which 9000 of the enemy were left dead on the field. The emperor Sigifmund, alarmcd at his progrefs, caufed very advantageous propofals to be offered to him; which he readily accepted, and fet out to meet Sigifinund, but died on the road. He ordered that his body fhould be left a prey to the birds and wild beafis; and that a drum flould be made of his akin, being perfuaded that the enemy would fly as foon as they heard the found. It is added, that the Huffites executed his will; and that the news of this order made fuch an impreffion on the diflurbed imaginations of the German Papitts, that in many battles they aetually fled at the beat of the drum with the utmon precipitation; leaving their baggage and artillery behind them.

ZinZiber, or Zingiber. See Amomum, Botaiy and Materia Mifdica Index.

ZION, or Stos, in Ancient Geography, a very famous mountain, flanding on the north fide of the city of Jerufalem. (Pfal. xlvii. 2.) ; containing the upper city, built by King David ; and where food the royal palace, (Jofephus). A part of Zion, fituated at its extremity, was called Millo, of or in the city of David, (2 Chron. xxxii. 5.) Modern travellers, who have been upon the foot, fay, that Zion is the whole of the mountain, on which Jerufalem flands at this day, though not to the extent in which it anciently flood on the fame mountain, as appears Pfal. ix. 12. 15. lxv. 1. Jxixxvii. 2, 3. If. 3xii. r. It is fwelled into feveral eminences or tops; as Moriah, Acra Bezetha, and Zion 2 particulareminence or mount, and Zion Proper, \&xc. encompaffed on three fides, eaft, weft, and fouth, with one continued very deep and fteep vallcy; by means of which it was impregnable on thefe three fides, and always attacked and taken, according to Jofephus, by the enemy on the north file, where Mount Zion became level, and the vales of Gihon and Jehofophat gradually lofe themfelves. This deep and fteep valley inconteftably conflitutes the compals of the old Jerufalem on thofe three Gdes, as plainly appears to any perfon who has been upon the fpot. On that particular top of the mount called Zion flood the fortrefs of the Jebufites; which being afietwards taken by David, came to be called the City of David, where he had his royal refidence and kept his court. That part of the valley which lay to the eaft was called Jehofophat's, having Mount Olivet
lying beyond it; that to the fouth Geltionons and that to the 'well, Gihon, from cognominal ntiountains lying be:yond them. At the weft end of Gihon, withour the city, flood Golgotha or Calvary. The pretended Golgotha, flown at this day within the walls, is the fpurious brat of interefted and fraudulent monks, (Korte). There is another Zion, the fame with Hermon.

Zion, or Zion College. See London, \(\mathrm{n}^{\circ} 76\).
ZiPH, or Siph, in Ancient Geograply, the name of a wildernefs or defert in the tribe of Judah, where David was fugitive; lying to the fouth-eaft of Hebron ; fo called from Ziph or Siph, a twofold town in this tribe; the one more to the fouth towards Idumea, on the confines of Eleutheropulis, (Jerome) ; the other eight miles to the eaft of Hebron, towards the Dead fea, incliting fouthwards, becaufe near Mount Carmel. Here was a mountain, mentioned 1 Sana. xxiii. 14 . in which David abode, faid by Jcrome to be rugged, difmal, and always overcaft. Ziphimn, Ziphar, or Ziphenfes, the inhabitante of Ziph, ver. 19.

ZIRCHNIT ZER-SEE, otherwife called the Lake of Czirknitr, in Carniola, is about one German or four Einglifh miles in length, and half as much in breadth, contains three beautiful iflands, and is encompafied at fome difance with mountains and forefs. But what is molt remarkable is, that it difappears generally once ayear, about St John's or St James's day, tunning off through holes or pits in the bottom; fometimes it difappears twice or thrice a-gcar, and fometimes even in winter if the weather be dry. On the other hand, it has been known to continue two or three years without running off. Of the holes or pits, there are five much larger than the ref, each of which fucceffively, when the water runs off, flands empty five days; fo that the whole lake becomes dry in 25 . As foon as the begin. ning of the ebb is oblerved, the fifhing in the pits begins, which belongs to five feigniories. The fint, which are carp, tench, pike, eels, and two other forts called fckleien and ruten, are caught by laying nets over the holes. Mr Keyller tells us, that upon the ringing of a bell at Zirknitz, when the waters begin to fall, the peafants, both men and women, run to the pools quite naked.

ZIRCON, a mineral fubftance containing a peculiar earth. See Mineralogy Index.
ZIRCONIA, a' peculiar earth. See Chlmistry Index.

ZIZANIA, a genus of plants of the clafs moncecia; and in the natural fyftem arranged under the \(4^{\text {th }}\) order, Gramina: See Botany Index.

ZODIAC, a broad circle, whofe middle is the ecliptic, and its extremes two circles parallel thereto, at fuch a diftance from it as to bound or comprehend the excur--fions of the fun and planets, (fee Astronomy). It is a curious enough fact, that the folar divifion of the Indian zodiae is the fame in fubflance with that of the Greeks, 'and yet that it has not been borrowed either from the Greeks or the Arabians. The identity, or at leaft Atriking fimilarity, of the divifion, is univerfally known; and M. Montucla has endeavoured to prove, that the Bramins received it from the Arabs." His opinien, we believe, has been very gencrally admitted; but in the fecond volume of the Afiatic Refearches, the accomplifhed prefident Sir William Jones has proved unanfuerably, that neither of thofe nations borrowed that divifion from the other; that it has been known among

Zodinc the Hindoos from time immemorial ; and that it was probably invented by the firt progenitors of that race, whom he confiders as the molt ancient of mankird, before their difperfion. The queftion is not of insportance fufficiently gencral, Araitened as we are by the limits prefcribed us, for our entering into the difpute; but we think it our duty to mention it, that uur aftrononical readers, if they think it worth their while, may have recourfe to the original writers for further information.

ZOEGEA, a genus of \(\mathrm{p}^{l l}\) ants of the clafs fyngenefia, See Botany Imdix.

ZONE, in Geography and Alronomy, a divifion of the terraqueous globe with refpect to the different degrees of heat found in the differcent parts thercof. The zones are denominated torrid, frigid, and temperate. The torrid zone is a baud, furrounding the terraqueous globe, and terminated by the two tropies. Its breadth is \(46^{\circ}\). 58'. The equator, running through the middle of it, divides it intu two equal parts, each containing \(23^{\circ} 29^{\prime}\). The ancients imagined the torrid zone uninhabitable. The temperate zones are contained between the tropies and the polar circles. The breadth of each is \(43^{\circ} 2^{\prime}\). .The frigid zones are fegments of the furface of the carth; terminated, one by the antarctic; and the other by the artic circle. 'The breadth of each is \(46^{\circ} 58^{\prime}\).

ZOOLOGY, is that part of natural hitory which selates to animals. See Natukat. History.

ZOOPHYIES., The name Zoopirytes, Zoophyia (i. e. animal plants, from Gacr, animal, and. фviov, plant), has been long appropriated to a numerous affemblage of marine or aqueous productiors, which have puzzled the ingenuity of naturalifts to afcettain their place in the chain of nature's works, and which have been alternately ranked among vegetable and animal, and fometimes even among mineral fubftances. At length, however, they feem, by general confent, to have been configned over to the animal kingdom, and, with the addition of feveral tribes from the Linnæan orders of Intefina, Mol-
verfe fepla are of unequal heights. The colvur of the mafe 7onjing een is a decp purple, or a rich crimfon. 'i he fize of the rad's varies confiderably; but fpecimens have leen abrained of from a foot to three feet in diamcter. It is found abundantly in the Pucific ocean, and on the faures of tume of the illands in the Indian fea.

In its recent flate it is cuvered with a mucous or gelatinous fubflance, which pervades the whole mals and cnters within cach tube. The inhabiting animal is not certainly afcertained, but leerns to be allied to the ner eis trise.

Figs. 3. and 4. exhihit two views of the Matukt. 1endreparz rors fungies, or mifuroon madrepore. ' This body io 'ung tcso exactly relembles a mulluroom, that it has very conamp!-fig. 3. \& 4. ly been regarded as, that vegetable in a flate of perrifaction; but recent obfecvations leem to prove that it is formed by limall animals like medufe. 'the couses fide of this madrepore is conical, fometimes roblufeiy pointed, and exhilits on its furface thefe llellaird prates waich form the dillinguithing character of the genue, while the concave furface is divided into numerous radialed furrows fo as io reprefent the gills of a muthroom. When fitt obtained, it is of a delicate white culour, efpecially on the concave part, but it foon acquires a brown or yellowint tinge. It is found of various fizes, from an inch to fix inches in diameter. It is met with chiefly in the Indian ocean and Red lea.

At fig. 5. is reprefonted that elegant coral called by Ifis biphuLinnæess lsis hippuris, the black and white jomed corol ris. of Ellis. The lperific character of this coral is that it \({ }^{\text {lig. }} 5.8\). 6 . is compofed of white Ariated joines urited by block junctures; but this Aructure is not vifible till ster the coral has been freed from a whitioh foft f:pongy part, witls which the branches are covered in their natural fiate. See fig. 6. It is found chieily in the Irdian feas, and varies in height from a few incles to neatly two feet.

Fig. 7. reprefents the ANTMPATMIS myitiophylla, yor- An*itathe, row antipathes, or fea-yarrow, of is natural lize; while myraphy'fig. 8. flews one of the pinnec confiderably magnified.
tufca, and Infuforia, have, by Cuvier and his colleagues of the French fchool, been elevated to the rank of a feparate clafs. Sce Helminthology, \({ }^{0} 1\) i.

In the Linnzan fyftem; the zoophytes of earlier mo. dern naturalifts conftitute the 4 th order of the clafs Virewes, and as fuch have been enumerated under HelwinrHoLOCY; but as the circumferibed limits of that article did not admit of our defcribing or figuring many fpecies, we fiall now as far as poffible fupply that deficiericy by felecting a few of the moft curious or interefting feecies of the Linnean zoophytes; and we fhall take this opportunity of making a few oblervations on fome of the genera to which they belong.

Figs. 1. and 2. reprefent the Tubipora mufica, iis. \& from its congeners by having the tubes connedied inio Mig. I. \& 2.fofficutlee or bundles, and feparated from each other by tranfserfe. membranous partiions. . The whole maifs
confifts of upright parallel tuben, rifing over each other 1 ranfurfe. membranous partiions. . The whole mafs
confift of upright parallel tubes, rifing over each other bv flages; fomething like the cells of a honeycomb. There tubes vary in height from half an inch to ar inch; and are from one-tenth to one-eighth of an inch in diameter. Examined internally, they appear to contain a fmaller tube divided at certain diflances by radiated nartitions (fee fig. 2.), by means of which the tranfverfe fipte fometimes conamunicate with each other. .Thele tranf-

This is one of thole zoophytes which in their habit and appearance almoit cxactly refemble fome of the vegetable tuibes, and hence have received the names of feaheath, fea-cyprefs. fea-fennel, \&e. From their calour they are ufually denominated black coral. This fpecies, though one of the fmalled, is not the leaft elegant of the tribe. It confilts of numerous branches, compofed of very flender pinnee arranged in no certain order. The whole coral is feldom above a foot in height, and rough on its outer furface. This allo is a native of the Indiar ocean, being found more efpecially on the coafts of the Molucca inlands, and is fometimes met with in the Great South fea.

Fig. 9. exhibits a fpecimen of red coral, the Isis noli-Gorstor:s lis of Linné, and GORGONIA nebilis of later naturalifts, nobilis. This fubftance, though now nearly exploded from the Fig. 9. Siro. materio medica, will fill retain a place in our cabinets for its intrinfic beauly and elegant appeararce; but when examined on its pative beds, or foon after being fihed up, it the ins a very difierent furface from that under which we ufually fee it. Fig. 9. reprefenis it as prepared for fale by being deprived of its flefly amimal bark or coating, but retaining the friated appearance which marks its fpecific character; but fig. 10. exhibits a piece of it in its natural Itate, with polypes extruded from the fle \(h_{1 y}\) coat, and Gewing flill more difinety at the extremitics the ftreaks below.
\(\qquad\) Figs. I. and 2. reprelent the Tunipora mulica, of the fe fipulo pods 0 ion This pecies is disinguined from ingular productions.. This ipecies is dur - \(\sin A\)

Zomphytes. Red coral is' found in latge beds or reefs in feveral parts of the Mediterranean fea, and cora! filheries are eltablithed on the coatts and near the illands. A fifhery of this kind in the ftraits of Meflina is minutely defcribed by Spallanzani in his Travals in the two Sicilies, vol. iv. To tear the coral from the rocks they make ufe of a machine compoled of two beams tied acrofs each other, and furnifhed with a leaden weight to fink them, and a quantity of loofe hemp and feveral frong nets to entangle the branches of the coral. To this machine is attached a itrong rope, which is held by the filhers, and ferves both to direct the net and to draw it up when the coral is cntangled. Several boats go in company, each containing eight men, and the fiffery lafts from April to July. The quantity collected every year amounts on an average to twelve Sicilian quintals, each equal to 250 pounds Troy, and each pound ufually fells for about four hillings and fixpence. They do not filh on the fame bank oftener than once in ten years, as this time is dcemed neceffary for the coral to acquire its full fize and vigour.

Another beautiful fpecies of gorgonia, the GorgoNia ceratophyta, is figured at fig. II. This is diftinguilhed by its dichotomous fatilfo fem, and afcending branches. The outer flefh is of a purplifh colour, and the branches are furnighed with two rows of fcattered pores from which the polypi appeat. It is found in the Mediterranean, and fometimes on the eaftern coafts of America.
Alcyonium gargonoides.
Fig. I2.
Nearly allied to the gorgonix is the fpecies of alcyonium reprefented at fig. 12. This is the Alcyonium gorgonoides of Gmelin. It is of a cinereous colour, of a fandy fefty confiftence, having radiated warty cellules. It is found on the northern coalt of South America, efpecially near the ifland of Curaçoa.

The zoophytes which naturalifts diftinguifh by the genesic name alcyonium, fometimes form independent bodies of a rounded form, fuch as thofe called the fea-orange, fea-fig, \&c.; or cover the furface of fhells and other marine bodies like a kind of bark. Their internal part or bafe is friable, and, when dried, appears to be compofed of fine fibres, which are either longitudinal, as in the prefent cafe, diverging, or circular. This bafe is covcred with a foft cruft, that in drying affumes a leathery confiftence, and is pierced with numerous little cells inliabited by polypi. In fome fpecies thefe cells are difperfed over the whole furface of the coral, while in others they are confined to particular fpots or tubercles. They are all inhabitants of the ocean, where they are ufually fixed to rocks or other folid bodies.
Sporgia
tubutofa.
In the article Helminthology we have fufficiently treated of the nature and properties of the fponges, and have there nientioned particularly the common or officiFig. 13. nalfponge. At fig. 13. is reprefented a more curious fpecies, the Sp. tubulofa or fiffularis, the tubular or pipcy fonge. This confifts of finale upright, attenuated, rigid tubes, luberculated on the outer furface, which is of a black colour. It is found in the feas that wafl the confts of America.
Ftufratre- The fluflre are a tribe of infignificant zoophytes, nsfa. Which feem farcely entitled to the rank which they Fig. 14. hold in the animal creation. They are formed of a conyeries of fuperficial cells, placed clufe together, like thofe of a heneycomb, but generally occupying only a fingle furfice. Sometimes this fubllance forms a coating to fome other marine body, at o:hers it is unattached and
forms a floating foliaccous mafs or mat., The fpecies re. 'zopligtes prefented at fig. 14. is one of the moft curious, and is defcribed by Ellis under the name of Englifh fea-mat, called in the Linncean Tranfactions, vol. v. Flustra arenofa. It is compofed of fandy particles agglutinated together with lline, and in thape refembles the fire part of a horfe's hoof. It is very friable, and fo thin as to be eafily broken. Thefe fluftrae are found abundantly on the coaft of Kent, and about Holy-head on the Welft coalt.
lig. 15. reprefents fpecimen of Sertularia fctacea, Sertularia the fmall fea-brifle coralline of Ellis, of its natural fize; celacea. and fig. 16. Thews the fame fpecimen confiderably mag. Fig. 15 nified. This pecies is diftinguifhed by being \(\sqrt{m} m p / y \& 15\). pinnated, with bent alternate pinnce, furnijbed wied qeery remote proceffes growing only on one fide, and cblong anillary ovaries. It is one of the favallelt and molt delicate of the tribe, feldom exceeding an inch and a half in height. It is very common, and is found on the litith coalts.

None of the zoophytes bear a nearer refemblance to vegttables than the fertularic. Their creeping roots, their branched ftem, and tufts of feeming flowers (the polypine proceffes) give them all the air of plants. Hence they were long confidered as fea-mofes, and defcribed by botanilts under that name. See liay's Synopfas, p. 38. and 39. When attentively examined, however, their animal nature will fcarcely be difputed. Externally they are compofed of a horny fubflance, perfectly tranfparent, and through this may be diftinguifhed the animal fubfance traverfing the centre of the ftem and branches like the pith of a plant, and appearing externally as little knots or protuberances in the form of tentaculated polypes. Thefe extraneous polypes are confidesed by Cuvier, (Tablean Elementaire, p. 768.) not as diftinct animals, but only as parts of the fame animal which conltitutes the fole inhabitant of the fertularia. Thefe zoophytes adhere to rocks, thells, \&c. by creeping roots, and appear to propagate by means of eggs. They are among the moft common of this clats of animared beings.

The Pennatul 2 or Sea pens confitute a very curi- Pennatula ous tribe of zoophytes, which are completely locomo-phojphorcs. tive, and fwim in the manner of filhes. They confilt of Fig. \({ }^{17}\). an internal bone or rather horny fubftance, covered with \& 18.
a Cenfible tlethy coat. Their lower extremity is fimple like the barrel of a quill, while the upper extremity is expanded into a flattened part, that is generally compofed of pinna like the barbs of a quill, though it is fometimes merely a fimple expanded mals furnifhed with polypine procefles.
- Fig. 17. reprefents one of the mon common fea-pens properly focalled, the Pexinatula phofphorea, phophoref. cent pennatula, of its natural fize. It has a felby fem, e rough middle part, and imbricated pinmules. The pinne are furnithed on one fide with leffer pinnulec, at the extremities of which appear the polypes. See fig. 18. which fhews one of the feparate pinnæ, a little magnificd. This fpecies is of a fine red or light fcarlet colour, and when alive exhibits a fong phofphorefcent light, fo as to render diftinety vifible objects that are nearit. It is pretty common on the coafts of Britain, and is fometimes taken in the filhermen's nets, or adhering to the baits.

For figures of two other linıran zonphytes. the Tubularia magnifica, and. Hydra viridio, fee Plate

ZOUTOMY, the art of difeeting animals or living creatures, being the fame with analomy. Sce Anato. Mr:
Z.ORILLE, a fpecies of weefel which inhabits Peru, and other parts' of South America; and is faid to be remarkable for its fetid odour.

ZOROASTER, or Zerdusht, a celcbrated ancient phinlofopher, faid to have been the reformer or the tounder of the religion of the magi. It is wholly uncortain to how many eminent meat the nane of Zoroafter belonged. Some have maintained that there was but one Zoroafter, and that he was a Perfian; others have faid that there were fix eminent founders of pinilofoplyy of this name. Ham the fon of Noah, Mofes, Ofiris, Mithras, and others, both gods and men, have by different writers been afferted to have been the fame with Zoroalter. Many different opinions have alfo been advanced concerning the time in which he flourifted. Ariftotle and Pliny fix his date at fo remote a period as 6000 years before the death of Plato. According to Laertius, he flourithed 600 years before the Trojan war; according to Suidas, 500. If, in the midft of fo much uncertainty, any thing can be advanced with the appearance of probability, it feems to be this; that there was a Zoroaller, a Perio-Median, who Hourifhed about the time of Darius Hyftafpes; and that befides him there was another Zoroafter, who lived in a much more remote period among the Babylonians, and taught them aftronomy. The Greek and Arabian writers are agreed concerning the exiftence of the Perfian Zoroafter; and the ancients unanimoufly alcribe to a philofopher, whom they call Zoroafer, the origin of the Chaldean aftronomy, which is certainly of much earlier date than the time of Hyftafpes: it feems, therefore, neceffary to luppofe a Chaldean Zoroafter diftinct from the Perfian. Concerning this Zoroafter, however, nothing more is known, than that he flourihed towards the beginning of the Babylonifh empire, and was the father of the Chaldean aftrology and magic. All the writings that have been alcribed to Zoroafter are unqueftionahly fpurious.

ZOSTERA, a genus of plants of the clafs gynandria, and in the natural fyttem arranged under the fecond order, Piperitc. See Botany Index.

ZOSIMUS, an ancient hiftorian who lived at the end of the fourth and beginning of the fifth century. There are fix books of his hiflory extant ; in the firf of which he runs over the Roman affairs in a very fuccinct manner from Augultus to Dioclefian ; the other five are written more diffufely. Zofimus was a zealous Pagan ; whence we fiid him frequently inveighing with great bitternefs againft the Chriftian princes, particularly againf Conftantine the Great, and the elder Theodofius. His hiifory has been publifhed with the Latin verfion of Leunclavius at Frankfort, 1590, with the other minor hiftorians of Rome, in folio; and at Os. ford in \(8 \mathrm{vo}, 1679\).

ZUG, a canton of Switzerland, bounded on the eaft and nori'h by that of Zurich, on the fouth by Schweitz and Lucern, and on the wefl by the canton of Lucern and the Frese-Amt or Free Provinces. It is not above 12 miles either way; but very populous and fruiful,
yielding wine, wheat, chefruts, and other fruit, in \(^{\dagger}\) its vales, and excellent prature on its mountains. The inhabitants of this cartun are (ीaunch Ioman Cathol!cs. It lies in the diocofe of Confance, and its government is demorraticai. "Jhere are two lakes in it abounding in fill, particularly large carps, pikes, and a fpecies of trouts called rotcls; as well as feveral woods full of gank. Zug, which gives name to it, and is its capital, Hand, on the ealt fide of a lake of the fame name, about fevela miles long, and is a frong neat town, containing a prioly and two convents.
ZUII, A, a town in the territory of "ezzan, in Africa, which thands on a fpace of about a mile in circuit, but was formerly of much greater extent. The environs are level, well fupplied with water, and fertile, planted with groves of date trees, and the inhabitants pay much attention to agriculture. N. Lat. 27. 2g. E. L.ong. 16.39.

ZUINGLIUS, Uiricus, an able and zealous reformer, who laid the foundation of a feparation from Rome in Switzerland, at the fame time that Luther did the like in Saxony, was born at Wildehaufen in 1487. While he officiated as preacher at Zurich, a Francifcan fent by Leo X. came to publifh indulgences there; againft which Zuinglius, after the example of Luther, declained powerfully. In the courfe of this oppofition he flarted a new doctrine, which he called Evangelical Truth; and from the beginning of 1519 to 1523, he preached not only againft indulgences, but againtt orher articles of the Romith church. But though Zuinglius made no lefs progre's than Luther, he conducted himfelf with more moderation and prudence; and wilhing to have the concurrence of the civil powers, procured two afiemblies to be called at Zurich : by the firft, he was authorifed to proceed as he had begurn; and by the fecond, the outward worftip and ceremonies of the church of Rome were abolifhed. During thefe tranfactions, Zuinglius publifted feveral books in defence of his doctrines; but treating of the eucharift, and prefcribing a form of celebrating the Lood's Supper different froraLuther, he was involved in violent difputes with the reft of his reforming brethren. Refpeling the divine DEEcrers, the opinion of Zuinglius and his followers differed very little from that of the Pelagiass: and inתead of declaring with Calvin, that the church is a feparate independent body, vefted witl the right of legiflation for itfelf, Zuinglius afcribed to the civil magiftrate an abfolute ard unbounded power in religious natiters, allowing at the fanme time a certain fubordination among the minifters of the church. This was abundantly agreeable to the magiftrates of Zurich; but the selt of the Swifs cantons difallowing of their proceedings, other affemblies were called, and things tending to tumult, both fides had recourfe to arms; when Zuinglius, who began as a preacher, died in arms as a foldier, in 153 . His works are in four volumes folio.
ZURICH, a canton of Sswitzerland, bounded to the north by Swabia and the canton of Schaffhaufen; to the fouth by the town and territory of Rapperichweil and the cantons of Switz and Zug; to the eall by the Thurgau, Toggenhurg, and Utzzach ; and to the weft by the free bailiages and county of Raden. It is about 60 miles from notth to fouth, and 48 from caft to weft. With refpeet to its face, air, and foil, it is faid to be an epitoree of all Switzerland, as containing in it hills, valleys,

Zurich.

\section*{Z U R [806] Z Y M}

Zurich. valleys, plains, corn-lands, vineyards, lakes, and rivers. Their wines have a tartnefs at firft, but the longer they are kept,the more agreeable they are. The other products are excellent fruits, corn, pafture, fine clay, chalk, feveral coloured earths, pit-coal, turf, and fulphur. There are alfo fome nineral fprings in the canton, and fome lakes; Zurich is the moft confiderable, it is 24 miles long, and two broad. The reformation was introduced here by Zuinglius in the year 1517 . This canton is the firft in rank, and inferior only to that of Bern in extent, power, and wealth; in confequence of which, its reprefentatives prefide in the general diets, when held in any place belonging in common to the cantons; and the affairs relating to the whole confedesacy are tranfacted in its offices. Its quota, for the defence of the feveral members of the confederacy, is 1400 men. Of one of the two armies raifed on thefe occafions, it nominates one of the commanders in chief, as Lucern does the other. Its revenue is faid to be about 150,000 crowns a-year ; of which, one year with another, two thirds are expended in the charges of government, and the reft laid up in the treafury. It can bring 50,000 fighting men into the ficld at a very fhort warning.

Zurich, the capital of a canton of the fame name in Switzerland, ftands in a pleafant country, near where the river Aa iffues from the lake that takes its name from the town, 23 miles from Schafthaufen, and 114 from Geneva. After having been ruined by Attila the IJun, it is faid to have been reftored by Thuricus, fon of Theodoric king of the Goths, from whom it took the name of Thuricum, corrupted afterwards into that of Zurich. It is fortified insthe modern way, and has wide ditches, faced with frec-ftone. There are five arfenals in it, well ftored with arms and artillery; an academy or college, having 15 profeffors; a mufeum, or chamber of rarities; a ftately town-houfe, the pillars in the front of which are of black marble, ftreaked with white; and a town library. The fovereignty and adminintration of all affairs are lodged in the greater and ?effer council, out of which are chofen the city-officers, as the councils are out of the 13 companies of burghers. There are feveral other councils or colleges, each of which has its particular department. Here are a great variety of filk, woollen, linen, cotton, and other manufactures; this being the place of the greateft tradc in all Switzerland. The town is well fupplied with provifions by and from its lake. The ftreets are neat, and houfes well built, but not magnificent. In the town-library are feveral letters to Bullinger from Lady Jane Gray, daughter to the duke of Suffolk. In one of the arfenals is the figure of William Tell, dreffed and armed in she ancient Swifs manner, with the crols-bow whence
he fhot the arrow that fruck the apple of his child's head.

Both men and women are fo fond of mufic, that there are few of them that cannot play on fome inftrument. If a burgher goes out of town, or a peafant enters it, without a fword, they are liable to be fined. No pe:fons, whatever their rank or office may bc, are exempted from the fumptuary laws. The burgomallers, who are the fame as the advoyers at Bern, have the title of cxcellence. The hofpitals here are neat and well endowed. The environs are pleafant and fruitful; for which it is not a little indebted to the lake. That past of it which is nea: Zurich is called the Lower Lake, and the other end the Upper. The cathedral, or great church here, is collegiate. The prefent city is faid to owe its origin to a numnery, founded by the emperor Lewis J. near where the ancient Tigurum food. E. Long. 8. \(300^{\circ}\) N. Lat. 47. 20.

ZUTPHEN, a frong and confiderable torm of the United Provinces in Guelderland, and capital of a counly of the fame name. It has a magnificent church, and is furrounded with walls. It was taken by the French in 1672 , who in 1674 delivered it up to the StatesGeneral. It is feated at the confluence of the rivers Berkel and Yeffel, nine miles fouth-eaft of Deventer, and 55 eaft by fouth of Amfterdam. E. Long. 6.0. N. Lat. 52.10 .

ZUYDER-ZEE, a grcat gulf or bay of the German ocean, which extends from fouth to nortb in the United Provinces, between Friefland, Over-Yeffel, Guelderland, and Hollond. It is fo called from its fituation towards the fouth. It is faid that the Zuyder-zee was formerly a lake, and that the land is fwallowed up which united North-Holland with Friciland.

ZYGOMA, a bone of the head, or rather an union or affemblage of two proceffes or eminences of bones. See Bones of the Head, under Anatomy.

ZYGOMATICUS, a mufcle of the head, arifing from the Os Zrgoms, whence its name, and terminating at the angle of the lips.

ZYGOPHYLLUM, Bean-CAPER, a genus of plants of the clafs of decandria, and in the natural fyltem arranged under the \(14^{\text {th }}\) order, Gruinales. See Botawy Index.

ZYMOSIMETER (formed from 乌ขusiss, fermeniation, and \(\mu\) rigar, meafure), an infrument propofed by Swammerdam, in his book Dc Refpiratione, with which to meafure the degree of fermentation occafioned by the mixture of different matters, and the degree of heat which thofe matters acquire in fermenting; the fame inftrument is employed to afcertain the heat of temperament of the blood of animals.
